This book contains information obtained from authentic and highly regarded sources. While all reasonable efforts have been made to publish reliable data and information, neither the author[s] nor the publisher can accept any legal responsibility or liability for any errors or omissions that may be made. The publishers wish to make clear that any views or opinions expressed in this book by individual editors, authors or contributors are personal to them and do not necessarily reflect the views/opinions of the publishers. The information or guidance contained in this book is intended for use by medical, scientific or health-care professionals and is provided strictly as a supplement to the medical or other professional's own judgement, their knowledge of the patient's medical history, relevant manufacturer's instructions and the appropriate best practice guidelines. Because of the rapid advances in medical science, any information or advice on dosages, procedures or diagnoses should be independently verified. The reader is strongly urged to consult the relevant national drug formulary and the drug companies' and device or material manufacturers' printed instructions, and their websites, before administering or utilizing any of the drugs, devices or materials mentioned in this book. This book does not indicate whether a particular treatment is appropriate or suitable for a particular individual. Ultimately it is the sole responsibility of the medical professional to make his or her own professional judgements, so as to advise and treat patients appropriately. The authors and publishers have also attempted to trace the copyright holders of all material reproduced in this publication and apologize to copyright holders if permission to publish in this form has not been obtained. If any copyright material has not been acknowledged please write and let us know so we may rectify in any future reprint.

Except as permitted under U.S. Copyright Law, no part of this book may be reprinted, reproduced, transmitted, or utilized in any form by any electronic, mechanical, or other means, now known or hereafter invented, including photocopying, microfilming, and recording, or in any information storage or retrieval system, without written permission from the publishers.

PART 1 HISTORY AND PRACTICE OF FORENSIC PSYCHIATRY **1**

Robert Weinstock and Gregory B. Leong

1 A conceptual framework for forensic psychiatry 3
Richard Rosner
2 Defining forensic psychiatry: Roles and responsibilities 7
Robert Weinstock, Gregory B. Leong, Jennifer L. Piel, and William Connor Darby
3 History of forensic psychiatry 15
Marvin Thomas Prosono
4 Forensic psychiatric report writing 33
Michael A. Norko and Alec Buchanan
5 Guidelines for courtroom testimony 43
Phillip J. Resnick and Jennifer L. Piel
6 Practical issues in forensic psychiatric practice 51
Robert L. Sadoff
7 Education and training in forensic psychiatry 59
Rusty Reeves, Richard Rosner, John Gunn, David Reiss, and Dominique Bourget
8 Forensic psychiatric ethics 65
Robert Weinstock, William Connor Darby, Philip J. Candilis, Gregory B. Leong, and Jennifer L. Piel
9 What makes it right: Foundations for professional ethics 79
Richard Rosner
10 Liability of the forensic psychiatrist 83
Daniel Bonnici, Kate Bolton Bonnici, Robert Weinstock, and Thomas Garrick
11 The death penalty 91
Michael L. Perlin and Alison J. Lynch
12 Competence assessments 99
Jennifer L. Piel, Gregory B. Leong, and Robert Weinstock
13 Psychological autopsy and postmortem toxicology in forensic psychiatry 105
Andrew Kim, Mace Beckson, Alan Wayne Jones, and Alan L. Berman

PART 2 LEGAL REGULATION OF PSYCHIATRIC PRACTICE 113

Christopher R. Thompson

14 Informed consent and competence 115
Praveen R. Kambam
15 Hospitalization: Voluntary and involuntary 125
Joseph R. Simpson and Vincenzo Carannante
16 Assisted outpatient treatment and outpatient commitment 131
Gary Tsai and Cameron Quanbeck
17 The right to treatment 145
Jeffrey L. Geller
18 Treatment refusal in psychiatric practice 155
Debra A. Pinals, Ariana Nesbit, and Steven K. Hoge
19 Confidentiality and testimonial privilege 165
Eric Y. Drogin and Kyle C. Walker
20 The duty to protect 175
Alan R. Felthous and Claudia Kachigian
21 Treatment boundaries in psychiatric practice and sexual misconduct in the therapist–patient relationship 185
Robert I. Simon
22 The law and the physician: Ill physicians 203
Michael Gendel and Paul D. Cooper
23 The law and physician prescribing of controlled substances 213
Gregory Sokolov
24 Court oversight of psychotropic prescribing in youth in state custody 219
Cory Jaques

PART 3 FORENSIC EVALUATION AND TREATMENT IN THE CRIMINAL JUSTICE SYSTEM 227

Alan R. Felthous

25 Forensic evaluation and treatment in the criminal justice system: Introduction 229
Alan R. Felthous
26 Jail diversion, specialty court, and reentry services: Partnerships between behavioral health and justice systems 237
Debra A. Pinals
27 Criminal competencies 247
Stephen G. Noffsinger and Phillip J. Resnick
28 Treatment for restoration of competence to stand trial 257
Kelly Goodness and Alan R. Felthous
29 Criminal responsibility 267
Alan R. Felthous
30 Post-adjudication evaluations and disposition of insanity acquittees 277
Li-Wen Lee
31 Presentencing evaluations 285
Alan R. Felthous

PART 4 CIVIL LAW 293

Richard L. Frierson

32 Specific issues in psychiatric malpractice 295
Robert Wettstein
33 Psychiatric disability evaluations, workers' compensation, fitness-for-duty evaluations, and personal injury litigation 307
Liza H. Gold, Jeffrey L. Metzner, and James B. Buck

34 Americans with Disabilities Act (ADA) evaluations 319
Patricia R. Recupero
35 Sexual harassment and gender discrimination 327
Liza H. Gold
36 Civil competencies 337
J. Richard Ciccone and Joshua C.W. Jones
37 Death, dying, and the law 347
M. Carmela Epright and Richard L. Frierson

PART 5 FAMILY LAW AND DOMESTIC RELATIONS 355

Stephen B. Billick and Bradley W. Freeman

38 Role of the psychiatric evaluator in child custody disputes 357
Steven J. Ciric and Stephen B. Billick
39 Termination of parental rights and adoption 373
Megan M. Mroczkowski and Stephen B. Billick
40 Child abuse and neglect 391
Suzanne M. Dupée
41 Juvenile delinquency 407
Eileen P. Ryan
42 Posttraumatic stress disorder in children and adolescents: Clinical and legal issues 415
Frank K. Tedeschi and Stephen B. Billick
43 Forensic aspects of suicide and homicide in children and adolescents 429
Peter Ash
44 The child as a witness 441
Suzanne M. Dupée
45 Neuropsychological assessment of children and adolescents: Clinical and forensic considerations 457
Laura J. Phillips and Ann C. Marcotte
46 Assessment and treatment of adolescent sex offenders 467
Lisa Murphy, J. Paul Fedoroff, and Gregg Dwyer
47 Juvenile competency to stand trial, competency attainment, and remediation 481
Eraka Bath and Shawn Sidhu
48 Evaluating adolescent culpability 491
Peter Ash
49 Forensic aspects of childhood bullying 499
Bradley W. Freeman

PART 6 CORRECTIONAL PSYCHIATRY 509

James L. Knoll

50 The history of correctional psychiatry in the United States 511
Peter N. Barboriak
51 Overview of correctional psychiatry 521
Charles L. Scott
52 The structure of correctional mental health services 529
Joel A. Dvoskin, Melody C. Brown, Jeffrey L. Metzner, Erin M. Nelson, and Steven E. Pitt
53 The architecture of correctional mental health law 551
Fred Cohen and James L. Knoll
54 Correctional psychiatry research 563
Bruce B. Way and Philip J. Candilis
55 Psychopharmacology in correctional settings 573
Kathryn A. Burns
56 Suicide in correctional settings: Epidemiology, risk assessment, and prevention 581
James L. Knoll and Andrew R. Kaufman

57 The right to refuse treatment in a criminal law setting 593
Michael L. Perlin and Naomi Weinstein
58 Hunger strikes by inmates 603
George David Annas

PART 7 AGGRESSION AND VIOLENCE 611

William Newman

59 Antisocial personality disorder and psychopathy 613
Anthony Maden and William Newman
60 Clinical assessment of aggression and violence 623
Charles L. Scott and Phillip J. Resnick
61 Clinical management of aggression and violence 633
William Newman and Kenneth Tardiff
62 Mass murder 643
James L. Knoll, William Newman, and Brian Holoyda
63 Terrorism 653
William H. Reid, Daniel J. Reid, and Chris E. Stout
64 Traditional stalking 663
Kang Choi and Mohan Nair
65 Cyberstalking and the Internet age 675
Kang Choi and Mohan Nair
66 Mental illness and firearms 681
Amy Barnhorst
67 Women and violence 689
Jessica Ferranti

PART 8 PSYCHOLOGICAL AND NEUROIMAGING ASSESSMENTS 699

Barbara McDermott

68 Use of psychological assessment tools in forensic psychiatric evaluation 701
Sanjay Shah and Randy K. Otto
69 Violence risk assessment: The state of the science 713
Jennifer L. Skeem and John Monahan
70 Sex offender risk assessment 721
Amy Phenix
71 Structured approaches to assessing malingering 729
Michael J. Vitacco and Holly E. Tabernik
72 Forensic neuropsychology 739
Kyle Brauer Boone
73 Neuroimaging and forensic psychiatry 749
Robert A. Schug and Leidy S. Partida

PART 9 SPECIAL TOPICS IN FORENSIC PSYCHIATRY 767

Susan Hatters-Friedman

74 Malingering 769
Phillip J. Resnick
75 Amnesia, hypnosis, and brainwashing 779
Giovana de Amorim Levin, John Bradford, A.G. Ahmed, and Sanjiv Gulati
76 Culture and forensic psychiatry 787
Alexander I.F. Simpson and Susan Hatters-Friedman

77 Geriatric forensic psychiatry 795
Brian A. Falls, Gen Tanaka, and Harold J. Bursztajn
78 Gender issues in forensic psychiatry 805
Renee M. Sorrentino and Susan Hatters-Friedman
79 Substance abuse and addiction 815
Gregory Sokolov
80 Sexually violent predator laws 823
Douglas E. Tucker and Samuel Jan Brakel
81 Clinical assessment and treatment of sex offenders 833
John Bradford, A.G. Ahmed, and Sanjiv Gulati
82 Torture and psychiatric abuse: Definition, ethics, and assessment 845
Ryan C.W. Hall and Richard C.W. Hall
83 Health care and the courts 855
Gregory Davis
84 Social media and the Internet 863
Cathleen A. Cerny, Delaney Smith, and Susan Hatters-Friedman
85 Working in private forensic practice 869
William H. Reid
86 Social science, law, and psychiatry 879
Eugene Lee and Ann M. Killenbeck
87 Community-based interventions for justice-involved individuals with serious mental disorders 887
Robert L. Weisman, J. Steven Lamberti, and J. Richard Ciccone
88 Employee Retirement Income Security Act (ERISA) 897
J. Richard Ciccone

PART 10 BASIC ISSUES IN LAW 903

Robert Lloyd Goldstein

89 Philosophy of law: Classic and contemporary jurisprudence 905
Robert Lloyd Goldstein and Sanford L. Drob
90 Foundations of American law: The court system and the legislative process 911
Robert Lloyd Goldstein
91 Judicial review of the constitution: Search and seizure, smartphones, and protecting digital privacy 917
Robert Lloyd Goldstein
92 Tort law and the psychiatrist 923
J. Michael Heinlen
93 An introduction to civil procedure 931
Robert Lloyd Goldstein
94 An introduction to significant issues in criminal procedure 937
Roger J. Bernstein and Robert Lloyd Goldstein
95 Theories of legal punishment and contemporary trends in sentencing 949
Robert Lloyd Goldstein and Roger J. Bernstein
96 Forensic research on the Internet 957
Peter Ash and Paul J. O'Leary

PART 11 LANDMARK CASES IN FORENSIC PSYCHIATRY 963

Merrill Rotter

97 Introduction: The case for landmark cases 965
Howard Forman and Merrill Rotter
98 Civil, juvenile justice and family law cases 967
Meryl B. Rome and Andrew J. Rader
99 Criminal law and forensic psychiatry 977
Howard Owens and Jeremy Colley

100 Legal regulation of psychiatry 999
James W. Hicks
101 American Academy of Psychiatry and the Law Landmark Cases by Category as of 2014 1021

Subject index **1025**

Case index **1057**

Preface to the first edition

Principles and Practice of Forensic Psychiatry is the most ambitious publication to date of the volumes edited for the Tri-State Chapter of the American Academy of Psychiatry and the Law (AAPL). The Tri-State Chapter is the first and largest of the AAPL chapters. It draws upon the academy's resources in Connecticut, New Jersey, and New York. The Chapter provides more than 50 hours of formal training in forensic psychiatry each year through its two-semester course on forensic psychiatry and its January weekend program devoted to a specific single theme in the field. Having produced seven prior books, all in the series *Critical Issues in American Psychiatry and the Law*, the current volume is a natural extension of the Tri-State Chapter's educational work.

The literature in forensic psychiatry in the United States has grown, especially since the creation of AAPL in 1969. There are books to serve as introductions to forensic psychiatry for general psychiatrists, as research reports and monographs on specialized single topics, as compendia of legal cases and materials, and as advanced surveys of one or several major themes in psychiatry and the law. However, until the present volume, none of the existing books has been specifically designed to review the entire field of forensic psychiatry at a level consistent with the needs of subspecialists.

The American Psychiatric Association recently decided to recognize forensic psychiatry as a subspecialty and to petition the American Board of Psychiatry and Neurology (ABPN) to offer an examination for certification in "added qualifications in forensic psychiatry." The ABPN requested, and was granted, authorization from the American Board of Medical Specialties to proceed with the development and implementation of such a subspecialty examination. The increased professional recognition of forensic psychiatry makes greater the need for the present volume.

Principles and Practice of Forensic Psychiatry is designed as a foundation work in the field. Among the intended audience are (1) fellows in a fifth-postgraduate-year fellowship program in forensic psychiatry; (2) forensic psychiatrists preparing for the subspecialty examinations of the American Board of Forensic Psychiatry or the forthcoming "added qualifications in forensic psychiatry" examination of the ABPN; and (3) forensic psychiatric practitioners who want a convenient, one-volume reference book to assist them in their work. Forensic psychologists, forensic clinical psychiatric social workers, mental health administrators, and attorneys will also find the current volume to be valuable. The editors and authors have sought to set forth areas of general agreement (wherever possible) and to describe as fairly as is feasible the major contending views on those topics that lack consensus.

The current book attempts to be encyclopedic in scope. The AAPL and the American Academy of Forensic Sciences have endorsed the Accreditation Council on Fellowships in Forensic Psychiatry (ACFFP) and its standards for education and training in psychiatry and the law. The ACFFP Standards (AAPL 1982) set forth the main areas in the didactic core curriculum of forensic psychiatry as

1. Legal Regulation of Psychiatry
2. Criminal Forensic Psychiatry
3. Civil Forensic Psychiatry, including Family Law and Domestic Relations
4. Correctional Psychiatry
5. Special Issues in Forensic Psychiatry
6. Basic Issues in Law
7. Landmark Cases in Mental Health Law

It is in the sense of addressing all of these main topics identified by the ACFFP that this book is meant to be comprehensive.

Each author was asked to employ the uniform conceptual framework for the analysis of problems in forensic psychiatry that was introduced in the Tri-State Chapter's first book (Rosner 1982):

1. Identify the specific psychiatric-legal issue(s).
2. Identify the specific psychiatric-legal criteria that are used to decide the issue(s).
3. Identify the specific clinical data that are directly relevant to the psychiatric-legal criteria.
4. Set forth and explain the specific reasoning processes to be used to apply the data to the criteria to decide the issue(s).

Individual authors have adhered to this framework in their chapters to a greater or lesser degree, depending on their subject matter. It provides a uniform reference for

approaching the otherwise almost dauntingly diverse contents of the field of forensic psychiatry.

Part 1, History and Practice of Forensic Psychiatry, introduces the reader to the conceptual framework of the field, the definition of forensic psychiatry, such practicalities as report writing and courtroom testimony, current educational and ethical standards, issues in administration, potential abuse of psychiatry, the death penalty, psychological autopsies, criminal profiling, competence assessments, and the history of forensic psychiatry.

Part 2, Legal Regulation of Psychiatric Practice, addresses informed consent, psychiatric hospitalization, outpatient civil commitment, the right to treatment, the right to refuse treatment, confidentiality and testimonial privilege, the duty to protect third parties, treatment boundaries, sexual misconduct by therapists, and the impaired physician.

Part 3, Forensic Evaluation and Treatment in the Criminal Justice System, considers criminal competencies, criminal responsibility, trauma-induced psychiatric disorders, and postconviction dispositional evaluations.

Part 4, Civil Law, examines psychiatric malpractice, psychiatric disability determinations, personal injury litigation, trauma-induced psychiatric disorders, evaluation of neurotoxicity, testamentary capacity, guardianships, and issues at the end of life.

Part 5, Family Law and Domestic Relations, reviews child custody, abused children, abused elders, juvenile delinquency, children in need of supervision, confidentiality, trauma-induced psychiatric disorders, fetal and infant issues, juvenile suicide, psychiatric hospitalization of minors, and adolescent violence.

Part 6, Correctional Psychiatry, focuses on the history of correctional psychiatry, standards for correctional mental health services, the structure of correctional mental health services, administrative issues, suicide prevention, inmate riots, and the ethics of correctional psychiatry.

Part 7, Special Clinical Issues in Forensic Psychiatry, explores malingering, antisocial personality disorder, dangerousness, causes and treatments of violent behaviors, epilepsy and brain disease, neuropsychiatric aspects of forensic psychiatry, psychological assessment, cultural and ethnic minorities, hypnosis, multiple personality disorder, amnesia, amytal, polygraphy, geriatric forensic psychiatry, torture, brainwashing, terrorism, AIDS (acquired immunodeficiency syndrome), and sexual offenders.

The Tri-State Chapter of the American Academy of Psychiatry and the Law offers *Principles and Practice of Forensic Psychiatry* as its latest educational contribution for students and practitioners.

ACKNOWLEDGMENT

The idea for this book originated with Robert Weinstock, MD, who presumed on 30 years of friendship with the editor to urge that a comprehensive textbook of forensic psychiatry be planned and implemented as a project of the Tri-State Chapter of the American Academy of Psychiatry and the Law.

Preface to the second edition

Principles and Practice of Forensic Psychiatry, *Second Edition*, was authorized by, and edited for, the Tri-State Chapter of the American Academy of Psychiatry and the Law (Tri-State AAPL). With one exception, every chapter in the book is an updated, revised, and expanded version of what appeared in the original edition, or is completely new. The one exception is the first chapter, which has been described as a "classic" statement of the Tri-State Chapter's approach to forensic psychiatry.

The Tri-State AAPL was conceived at the 1975 Boston, Massachusetts meeting of the national organization. There was initial skepticism among senior practitioners about the prospects for a local chapter of AAPL because a prior New York forensic psychiatry educational group, the Isaac Ray Society, had failed to thrive. There was initial opposition from national AAPL because of concern that local chapters might become competitors for members and dues. It was decided to poll by mail all of the AAPL members in New York State to determine if there was interest in the formation of a local forensic psychiatry society; the results of the poll indicated strong support. An organizational meeting was held, to which all New York State members of AAPL were invited. At that meeting, it was determined to call the new society the New York State Membership Group of AAPL because national AAPL had indicated that the then-bylaws of AAPL did not permit the creation of official chapters. The initial organizational meeting also generated a slate of candidates for elective office in the new society, and a mail ballot was sent to all New York State AAPL members; the election yielded the first officers of the new society. It was decided that there would be no membership dues, and that all AAPL members residing or working in New York State would automatically be members of the New York State Membership Group of AAPL.

The interest of AAPL members in New Jersey and Connecticut in participating in the educational programs of the New York State Membership Group led to a motion to expand the society. A mail ballot was sent to all AAPL members in New Jersey and Connecticut, inquiring if they wished to join a Tri-State Membership Group of AAPL; the results of the poll indicated firm support, and the society was expanded accordingly. In subsequent elections, care was taken to ensure that at least one representative from New Jersey and one representative from Connecticut were officers of the society.

The success of the Tri-State Membership Group led to a request that national AAPL authorize the creation of local chapters. An AAPL Task Force on Chapters was appointed and recommended that an appropriate bylaws modification be developed and submitted for ratification to the AAPL membership. On May 4, 1980, following approval of the new bylaw authorizing local chapters, AAPL authorized the Tri-State Membership Group to be re-named and recognized as AAPL's first official chapter: the Tri-State Chapter of AAPL.

The educational core of Tri-State AAPL has been its annual one-day educational program each January and its annual two-semester course on forensic psychiatry. As an outgrowth of those training programs, Tri-State authorized the publication of a number of books, all in the series *Critical Issues in American Psychiatry and the Law.* It is a source of great satisfaction to present the latest book authorized by Tri-State AAPL, the second edition of *Principles and Practice of Forensic Psychiatry.*

ACKNOWLEDGMENTS

Once again, Robert Weinstock, MD, has been the driving force behind this publication project. It was he who presumed on 40 years of friendship to oblige the editor to plan and implement this book.

Abraham Halpern, MD, has earned special citation for generously volunteering to read and edit the entire text for spelling, grammar, and legal citations.

Preface to the third edition

Principles and Practice of Forensic Psychiatry, Third Edition, was authorized by, and edited for, the Tri-State Chapter of the American Academy of Psychiatry and the Law (Tri-State AAPL). This third edition provides substantial revisions and additions to the second edition, and offers the reader the most current knowledge on a vast array of over 100 topics in the field of forensic psychiatry. With one exception, each chapter is either an updated version of what appeared in the original edition or is completely new. The one exception is the first chapter titled "A Conceptual Framework for Forensic Psychiatry," which has been described as a "classic" statement of the Tri-State Chapter's approach to forensic psychiatry. The Tri-State Chapter is the first and largest of the American Academy of Psychiatry and the Law (AAPL) Chapters.

As was the goal of prior editions, this third edition strives to be encyclopedic in scope and a foundation work in the field. Because of the significant expansion in the breadth and detail of material covered, this edition provides a practical source of information for a wide-ranging audience. Among the intended audience are (1) general psychiatry residents who are required to have exposure to a range of forensic psychiatric topics in their general training, (2) forensic psychiatry fellows in a fifth-postgraduate-year fellowship program in forensic psychiatry, (3) forensic psychiatrists preparing for the subspecialty examinations of the American Board of Psychiatry and Neurology's Added Qualifications in Forensic Psychiatry Examination, and (4) forensic psychiatric practitioners who want a convenient, one-volume reference book to assist them in their work. In addition, forensic psychologists, forensic clinical psychiatric social workers, mental health administrators, attorneys, and judges will find the current volume to be valuable. Although the information provided within this text is not meant to suggest a single standard of forensic psychiatric evaluation or treatment, the provided material will likely assist providers and practitioners in applying updated information as relevant to individual evaluations, policy development, expert witness testimony, and treatment planning.

Each author was asked to employ the uniform conceptual framework for the analysis of problems in forensic psychiatry that was introduced in the Tri-State Chapter's first book (Rosner 1982):

1. Identify the specific psychiatric-legal issue(s).
2. Identify the specific psychiatric-legal criteria that are used to decide the issue(s).
3. Identify the specific clinical data that are directly relevant to the psychiatric-legal criteria.
4. Set forth and explain the specific reasoning processes to be used to apply the data to the criteria to decide the issue(s).

Individual authors have adhered to this framework in their chapters to a greater or lesser degree, depending on their subject matter. It provides a uniform reference for approaching the otherwise almost dauntingly diverse contents of the field of forensic psychiatry.

This edition has expanded from nine to eleven sections, reflecting the growth of the forensic field. Part 1, History and Practice of Forensic Psychiatry, introduces the reader to the conceptual framework of the field, the definition of forensic psychiatry, history of forensic psychiatry, such practicalities as report writing and courtroom testimony, current educational and ethical standards and foundations of professional ethics, liability of the forensic psychiatry, death penalty, psychological autopsies, and competence assessments.

Part 2, Legal Regulation of Psychiatric Practice, addresses informed consent, psychiatric hospitalization, assisted outpatient commitment, the right to treatment, treatment refusal in psychiatric practice, confidentiality and testimonial privilege, the duty to protect third parties, treatment boundaries in psychiatric practice, and the impaired physician. Two newly added chapters to this section review laws related to physician prescribing of controlled substances and court oversight in psychotropic prescribing of youth in custody.

Part 3, Forensic Evaluation and Treatment in the Criminal Justice System, includes seven chapters addressing a range of evaluations for individuals facing criminal charges. Original chapters added to this section highlight emerging trends in jail diversion and speciality courts, treatment approaches for trial competency restoration, and the role of forensic evaluators in presentencing evaluations.

Part 4, Civil Law, examines psychiatric malpractice, psychiatric disability determinations, workers' compensation, personal injury litigation, sexual harassment and gender discrimination, civil competencies, and issues related to death and dying.

Part 5, Family Law and Domestic Relations, reviews child custody, termination of parental rights, abused children, juvenile delinquency, posttraumatic stress disorder in children and adolescents, forensic aspects of suicide and homicide in children and adolescents, the child witness, neuropsychological assessment of children and adolescents, and juvenile sexual offenders. Important additions to this section from prior editions include juvenile competence to stand trial and remediation, evaluations of youth culpability, and forensic aspects of childhood bullying.

Part 6, Correctional Psychiatry, focuses on the history of correctional psychiatry, standards for correctional mental health services, the structure of correctional mental health services, administrative issues, suicide prevention, inmate riots, and the ethics of correctional psychiatry. This third edition provides new chapters related to conducting psychiatric research and the use of psychopharmacology in a correctional setting.

Part 7, Aggression and Violence, is a completely new section to this edition that expands topics from other sections in prior editions. This section highlights the assessment and treatment of aggression, the assessment and treatment of antisocial personality disorder and psychopathy, terrorism, and stalking. Important and timely additions in this section include mental illness and firearms, individuals who commit mass murder, cyberstalking, and women who are violent.

Part 8, Psychological and Neuroimaging Assessments, is the second completely new section that recognizes the relevance of psychological testing and neuroimaging in conducting forensic evaluations. This section provides a practical overview to the use of psychological testing, with specific chapters highlighting the use of psychological testing in malingering assessments, sex offender risk assessments, and violence risk assessments. In addition, chapters highlighting the use of neuropsychological testing and neuroimaging in forensic psychiatric evaluations are provided.

Part 9, Special Topics in Forensic Psychiatry, includes a wide range of important topics in forensic psychiatry, such as the assessment of malingering, amnesia, cultural issues, geriatric evaluees, use of torture, terrorism, and issues related to health care and the courts. Newly added topics to this section include gender issues in forensic psychiatry, starting a forensic psychiatric practice, social science and forensic psychiatry, social media and the Internet, and community-based assessment and treatment of justice-involved individuals with mental illness.

Part 10, Basic Issues in Law, provides a useful overview for readers on the foundations of American law and the court system, philosophy of the law, criminal and civil procedure, theories of legal punishment, forensic research and the Internet, tort law and the psychiatrist, and judicial review of the constitution.

Part 11, Landmark Cases in Forensic Psychiatry, offers an extremely helpful summary of key civil and criminal law cases that involve a range of mental health issues, forensic assessments, and the provision of mental health care.

In summary, the third edition of *Principles and Practice of Forensic Psychiatry* provides an extensive overview of a wide range of topics designed to assist the forensic practitioner in maintaining currency in the field of forensic psychiatry.

The third edition of *Principles and Practice of Forensic Psychiatry* was edited for the Tri-State Chapter of the American Academy of Psychiatry and the Law. The editors are appreciative that the Tri-State Chapter of the American Academy of Psychiatry and the Law offers *Principles and Practice of Forensic Psychiatry* as its latest educational contribution for students and practitioners.

Officers of the Tri-State Chapter at the time of this publication are as follows:

Medical Director and Founding President	Richard Rosner MD
President	Manuel Lopez-Leon MD
Vice President	Bipin Subedi MD
Secretary	Susan Gray MD
Treasurer	Robert L. Goldstein MD JD

Councillors
Ziv Cohen MD
Jeremy Colley MD
Sundeep Randhawa MD
Frank Tedeschi MD
Emily Urbina MD
Jonathan Weiss MD

Acknowledgments

As with the first and second editions, Robert Weinstock, MD, deserves special recognition as a major driving force for the third edition of this book. His encouragement and friendship to both editors provided inspiration and motivation for this project. In addition, David Spagnolo and Hillary Brown of the University of California, Davis, Division of Psychiatry and the Law, are greatly appreciated for all of their organizational skills and efforts in preparing this book for submission.

Editors

Richard Rosner, MD, is a Distinguished Life Fellow of the American Psychiatric Association, a Fellow of the American College of Psychiatrists, a Distinguished Fellow of the American Academy of Forensic Sciences, and a Fellow of the American Society for Adolescent Psychiatry. He is a clinical professor in both the Department of Psychiatry and the Department of Child and Adolescent Psychiatry at the New York University School of Medicine. Rosner served as the first and only Associate Commissioner for Forensic Psychiatry of the Department of Mental Health, Mental Retardation, and Alcoholism Services of the City of New York. He is a former medical director of the Forensic Psychiatry Clinic for the New York Criminal Court and Supreme Court (First Judicial District) of Bellevue Hospital Center, New York. He co-founded and is a former director of the Forensic Psychiatry Fellowship Program at New York University Medical Center. Rosner is a recipient of the Isaac Ray Award of the American Psychiatric Association. He is a former president of the following professional organizations: the American Academy of Psychiatry and the Law, the American Academy of Forensic Sciences, the Association of Directors of Forensic Psychiatry Fellowships, the Accreditation Council on Fellowships in Forensic Psychiatry, the American Board of Forensic Psychiatry, Inc., and the American Society for Adolescent Psychiatry. Rosner was the founding president and is the current medical director of the Tri-State Chapter of the American Academy of Psychiatry and the Law.

Charles L. Scott, MD, is chief of the Division of Psychiatry and the Law, Forensic Psychiatry Fellowship Training Director, and professor of Clinical Psychiatry at the University of California, Davis, Medical Center in Sacramento, California. He is board certified in Forensic Psychiatry, General Psychiatry, Child and Adolescent Psychiatry, and Addiction Psychiatry. Scott is a past president of the American Academy of Psychiatry and the Law and is also past president of the Association of Directors of Forensic Psychiatry Fellowships. He has served as a member of the American Academy of Psychiatry and the Law national task force to develop guidelines for the evaluation of criminal responsibility and competency to stand trial. He is also one of four national American Academy of Psychiatry and the Law Forensic Psychiatry Review Course faculty instructors, and in 2008 received the American Academy of Psychiatry and the Law award as the most outstanding forensic psychiatry fellowship program instructor in the United States. Scott has served as a forensic psychiatric consultant to jails, prisons, maximum security forensic inpatient units, California Department of State Hospitals, and to the National Football League, providing training on violence risk assessment for National Football League counselors. He has been an editor and co-editor of four books related to forensic psychiatry and has published articles and book chapters in the areas of risk assessment of violence and aggression, the death penalty, juvenile violence, and mental health law. His research interests include the relationship of substance use to aggression among criminal defendants and the quality of forensic evaluations of criminal responsibility. He lectures nationally on the topics of malingering, violence risk assessment, juvenile violence, substance use and violence, the assessment of sex offenders, correctional psychiatry, the *Diagnostic and Statistical Manual of Mental Disorders* (fifth edition) and the law, and malpractice issues in mental health.

1

A conceptual framework for forensic psychiatry

RICHARD ROSNER

INTRODUCTION

The third edition of this volume begins with a particular conceptual framework applicable to all problems in the field. This framework is designed to organize the extraordinarily wide range of factors that must be considered in the approach to forensic psychiatry, so as to make rational analysis systematic, uniform, and more likely to be effective.

The number of specific psychiatric–legal issues to consider is itself large. As set forth in the *Standards for Fellowship Programs in Forensic Psychiatry* (Rosner 1982a), they include the following:

- *Civil forensic psychiatry* including, at minimum, conservators and guardianships, child custody determinations, parental competence, termination of parental rights, child abuse, child neglect, psychiatric disability determinations (e.g., for social security, workers' compensation, private insurance coverage), testamentary capacity, psychiatric negligence and malpractice, personal injury litigation issues.
- *Criminal forensic psychiatry* including, at minimum, competence to stand trial, competence to enter a plea, testimonial capacity, voluntariness of confessions, insanity defense(s), diminished capacity, sentencing considerations, release of persons who have been acquitted by reason of insanity.
- *Legal regulation of psychiatry* including, at minimum, civil involuntary commitment, voluntary hospitalization, confidentiality, right to treatment, right to refuse treatment, informed consent, professional liability, ethical guidelines.

Similar areas are included in the more recent requirements of the Accreditation Council for Graduate Medical Education (see Chapter 7). There are many psychiatric–legal issues that forensic psychiatrists are asked to address, and my proposed model is a way to conceptualize these issues so that an opinion can be rendered.

For every psychiatric-legal issue, a variety of legal contexts exist in which the issue may occur. In the United States, there are 50 state jurisdictions, plus the District of Columbia, and federal and military jurisdictions. For each of those 53 jurisdictions, there is a separate set of legislated statutes, a separate sheet of judge-made case law, and a separate set of administrative codes. As a result, the legal criteria that define a psychiatric–legal issue and establish the basis for its resolution are disparate and diverse.

A result of the multiplicity of issues, jurisdictions, and legal criteria is that there is no such entity as a general forensic psychiatric assessment. Rather, there is only a series of specific psychiatric–legal assessments, each focusing on one psychiatric–legal issue occurring in one legal context and determined by one set of legal criteria.

These legal considerations are in addition to the array of complex clinical phenomena that are the subject matter of psychiatry. The clinical materials are more diverse than is usually encountered in therapeutic practice because they address more than current, immediately accessible data. In some instances, the past is the issue; for example, what was the mental state of a defendant at the time that he or she confessed to the police? In other instances, the future is the issue; for example, which of two competing custodial parents is likely to be the better caregiver of an infant child as the child grows and develops to adulthood? In some instances, there is no one immediately available to examine, for example, in determining the mental state of the deceased person at the time that he or she signed his or her alleged last will and testament.

Compounding all of these matters is the need to present the practitioner's psychiatric–legal opinion as the result of a process of reasoned deliberation that is comprehensible and convincing to the majority of rational legal decision makers. It is not sufficient to offer a sincere belief; what is required is logically compelling knowledge. In clinical practice, when a patient's relative asks, "Will he recover, doctor?" it may be appropriate to respond, "I certainly hope so and I will do everything that I reasonably can do toward that goal." However, that would most likely be an inadequate answer

in a legal setting, where a reply supported by scientific facts and statistical projections might be what is expected. These more sophisticated facts must be presented in a systematic well-reasoned manner. It is not enough to know the materials; they must be organized in a logical, relevant, coherent fashion.

There are simply too many factors to be considered without a method for their more manageable organization. In much the same manner that all physicians are trained to organize the diversity of clinical phenomena so as to make them more amenable to rational assessment, forensic psychiatrists are trained to organize the diversity of psychiatric legal phenomena to facilitate their consideration.

For the clinical practitioner, the conceptual framework is some variation of identification, chief complaint, history of the present illness, pertinent past history, laboratory test data, differential diagnoses, and medical diagnostic impression. For the forensic psychiatric practitioner, the four-step conceptual framework is issue, legal criteria, relevant data, and reasoning process:

1. *Issue*: What is the specific psychiatric–legal issue to be considered?
2. *Legal criteria*: In the jurisdiction in which this specific psychiatric–legal issue must be resolved, what are the legally defined terms and criteria that will be used for its resolution?
3. *Relevant data*: Exactly what information (such as part of what might be collected by a clinician following the traditional clinical framework for data organization) is there that is specifically pertinent to the legal criteria that will be used to resolve the specific psychiatric–legal issue?
4. *Reasoning process*: How can the available relevant data be applied to the legal criteria so as to yield a rationally convincing psychiatric–legal opinion?

Among the virtues of a conceptual framework are that it facilitates: (a) the approach to the forensic psychiatric task to be accomplished; (b) communication among colleagues insofar as all colleagues are familiar with and use the same framework for the consideration of the forensic psychiatric work to be done; (c) the identification of areas that are unclear (e.g., the precise legal criteria for the specific issue); (d) the drawing of attention to areas that are incompletely addressed (e.g., the full range of clinical and factual data that are pertinent to the specific legal criteria); and (e) the determination of what are the bases of disagreements between different forensic psychiatrists (e.g., disagreements about the legal issue, about the legal criteria, about the relevant data, and about the reasoning processes).

It may be useful to give examples of how this approach is of practical value (Rosner 1982b,c,d, 1985, 1987, 1990). Suppose that a forensic psychiatrist is contacted by an attorney and is asked to provide an evaluation and report regarding a defendant. The forensic psychiatrist should ask the attorney exactly which psychiatric–legal issue or issues are to be addressed. Although the defendant is only one person, many distinguishable issues may be involved. The attorney may want an evaluation and opinion about a possible insanity defense, or about the defendant's mental competence to waive his or her *Miranda* rights at the time of a supposedly voluntary and knowing confession, or about the defendant's current competence to stand trial, or about the defendant's future competence to abide by the terms of probation.

If the forensic psychiatrist does not know exactly which issue to consider, there is no way to proceed with the evaluation. Pursuing the wrong issue would waste time and money and would jeopardize the outcome of the defendant's case. It is incumbent upon the forensic psychiatrist to clarify for the lawyer that there is no such thing as a general forensic psychiatric examination, and that the lawyer must specify which issue is to be the focus of the psychiatric–legal evaluation. If need be, several issues can be separately addressed, but each must be understood to be a distinguishable concern.

The forensic psychiatrist must also obtain from the lawyer the exact legal criteria, as established by statute, case law, and administrative code, that determine the specific issue in the jurisdiction that will hear the case. It may be easier to explain this point by analogy to the variable criteria that have been used at different times to make psychiatric diagnoses. Clinicians know that the American Psychiatric Association has employed several different manuals of diagnostic criteria over the course of time. To say that someone suffers from some type of schizophrenia according to the first (American Psychiatric Association 1952), second (American Psychiatric Association 1968), third (American Psychiatric Association 1980), third revised (American Psychiatric Association 1987), fourth (American Psychiatric Association 1994), fourth text revision (American Psychiatric Association 2000), fifth (American Psychiatric Association 2013), and forthcoming editions of the *Diagnostic and Statistical Manual of Mental Disorders* of the American Psychiatric Association is to say different things about that person depending on which set of diagnostic criteria is used.

It is possible that a person might be regarded as suffering from some form of schizophrenia according to one set of diagnostic criteria used at one time, but not according to a different set of diagnostic criteria used at a different time. In addition, the criteria used for clinical diagnoses may differ from nation to nation, although some standardization is achieved in those nations that agree to use the World Health Organization's periodically revised *International Classification of Diseases* (*ICD*). The clinical diagnosis is determined by the criteria used to make the diagnosis.

In an analogous manner, the legal criteria used to determine an issue have varied over time within any single place of jurisdiction, just as the clinical diagnostic criteria have varied over time within the United States. In addition, the legal criteria vary from place of jurisdiction (e.g., New York) to place of jurisdiction (e.g., Washington, DC) at the same time, depending on which legal place of jurisdiction is

hearing the case. It is uncommon for a forensic psychiatrist to have to be concerned with which legal criteria were used in the past, but it is both routine and of great importance to be concerned with which legal criteria are used in the specific place of jurisdiction that will hear the case.

A forensic psychiatrist must ask the attorney who wishes to retain him or her exactly which legal criteria are to be used to determine the specific psychiatric–legal issue in the jurisdiction that will hear the case. For example, the legal criteria to determine whether or not a defendant is not guilty by reason of insanity (NGRI) may vary from one jurisdiction to another. In one jurisdiction, the criteria for NGRI may address only whether or not the defendant was able to appreciate the nature and quality of his or her act, whereas in another jurisdiction that criteria may be supplemented by whether or not the defendant was able to conform his or her conduct to the requirements of the law. A defendant who might be found guilty in the first jurisdiction might be found NGRI in the second jurisdiction. A forensic psychiatrist practicing in two adjacent states might reach a different decision about the same case, depending on the location of the trial.

At minimum, the specific psychiatric–legal issue and the specific legal criteria will establish the time frame containing the relevant psychiatric data. The forensic psychiatrist may have to obtain data about the past, present, or future. Is the time frame an assessment of the defendant's mental state at the (past) time of the alleged offense for a potential NGRI defense? Is it an assessment of the defendant's mental state at the (not quite so past) time of his or her confession to the police so as to challenge the validity of the confession? Is the time frame the defendant's current mental state for a determination of his or her competence to stand trial? Is it the defendant's future mental state so as to determine if he or she will be able to comply with the conditions of possible probation?

Importantly, the legal criteria will often set forth exactly what kinds of information a person must have had (past), has (present), or will need to have (future) in order to resolve the specific psychiatric–legal issue. For NGRI, in some jurisdictions, the person must have had (past) knowledge of what he or she was doing and must have had (past) knowledge that what he or she was doing was legally wrong. For competence to stand trial, in some jurisdictions, the defendant must have (present) knowledge of the charges against him or her, and must have (present) knowledge of the nature of the legal proceedings against him or her. These criteria direct the forensic psychiatrist to make specific inquiries regarding the defendant's knowledge, and appreciation of that knowledge, at the relevant time period.

Often the legal criteria will also set forth the exact mental capacities a person must have had (past), has (present), or will need to have (future) to resolve the specific psychiatric–legal issue. For NGRI, in some jurisdictions, the person must have had the (past) capacity to conform his or her conduct to the requirements of the law. For competence to stand trial, in some jurisdictions, the person must have the (present) capacity to cooperate with an attorney in his or her own defense. These criteria direct the forensic psychiatrist to make specific inquiries regarding the defendant's non-informational mental abilities at the relevant time period.

The use of the forensic psychiatric conceptual framework can assist the practitioner in locating potential weaknesses in the case being developed. It may be that the attorney has been insufficiently specific regarding the exact psychiatric legal issue to be explored. It may be that the legal criteria are not set forth with clarity and exactitude. It may be that relevant data are lacking. It may be that the practitioner's reasoning processes have been less than logical.

A lack of training in logic may underlie the difficulty that some forensic psychiatrists may have in explaining the reasoning processes that are the bases of their psychiatric–legal opinions. In general, the structure of psychiatric–legal reasoning is familiar: The first step is the assertion of a law or law-like proposition. The second step is the assertion of a factual proposition. The third step is a deductive inference from those two propositions. For example, (a) humans are the only rational bipedal animals; (b) Socrates is a rational bipedal animal; (c) therefore, Socrates is human. If we apply this method to a psychiatric–legal example, we can see how the reasoning process works:

1. Persons who are competent to stand trial have the capacity to understand the charges against them, the capacity to understand the nature of the court proceedings against them, and the capacity to cooperate with an attorney in their own defense.
2. John Doe has the capacity to understand the charges against him, the capacity to understand the nature of the court proceedings against him, and the capacity to cooperate with his attorney in his own defense.
3. Therefore, John Doe is competent to stand trial.

Once the structure of the reasoning process is set forth, it is relatively easy to apply in the formulation of any psychiatric–legal opinion.

This structured reasoning process also reveals potential sources of legal challenge during cross-examination. An opposing attorney may challenge the truth of either of the two major premises, or may challenge the validity of the deductive inference. All premises may be challenged and all deductive inferences may be challenged; the question is whether or not such challenges will be successful. A soundly reasoned opinion is more likely to be successfully sustained than an opinion that is not based on sound reasoning.

This review of the reasoning process that must sustain a psychiatric–legal opinion demonstrates why it is so important to be certain of the specific legal criteria that determine the issue. The first premise is the statement of the specific legal criteria (i.e., the law or law-like proposition); the second premise is the summation of the available information that pertinently bears on the legal criteria (i.e., the factual proposition). If the first premise is wrong—that is, if the legal criteria used are incorrect—then the opinion is unsupported logically. If the second premise is wrong—that is, if

the available data are not relevant to the legal criteria—then the opinion is unsupported logically.

It is also possible that the two premises are correct and the deductive inference is wrong. For example, (a) all humans are rational bipedal animals; (b) Socrates is a rational bipedal animal; (c) therefore, Socrates likes chocolate.

A horrible example of such faulty deductive inference making in forensic psychiatry might be as follows:

1. Persons who are capable of understanding the charges against them, capable of understanding the nature of the court proceedings against them, and capable of cooperating in their own defense are competent to stand trial.
2. Richard Roe understands the charges against him, understands the court proceedings against him, and is able to cooperate in his own defense.
3. Therefore, Richard Roe was legally sane (and legally responsible) at the time when he committed the offense.

The conceptual framework for forensic psychiatry will assist a competent practitioner of forensic psychiatry in the cogent organization and presentation of the rational processes that are the foundation of his or her psychiatric–legal opinion. Just as the conceptual framework used by medical practitioners is not a guarantee that they will reach the correct diagnoses, the conceptual framework used by forensic psychiatrists is not a foolproof technique for reaching psychiatric–legal opinions. Rather, each is a tool for the organization of large quantities of complex data. In skilled hands, a tool will produce quality goods; in unskilled hands, a tool will produce shoddy results.

Defining forensic psychiatry: Roles and responsibilities

ROBERT WEINSTOCK, GREGORY B. LEONG, JENNIFER L. PIEL, AND WILLIAM CONNOR DARBY

INTRODUCTION

Forensic psychiatry operates at the interface of two disparate disciplines: law and psychiatry. Although most cases in forensic psychiatry practice engender no significant conflicts, functioning at the interface of these two disciplines can lead to confusion, challenging ethical dilemmas, or both. Forensic psychiatry received official recognition as a medical subspecialty by the American Board of Medical Specialties (ABMS) with the American Board of Psychiatry and Neurology (ABPN) granting its first forensic psychiatry certification in 1994. However, much work had been done prior to ABMS subspecialty recognition on defining the proper roles and responsibilities of forensic psychiatrists.

The modern era of forensic psychiatry might be considered to have started around the time of the establishment of the American Academy of Psychiatry and the Law (AAPL) in 1969. Pollack, who had established one of the earliest (if not the first) post-residency forensic psychiatry fellowship at the University of Southern California in 1965, stated "Forensic psychiatry is limited to the application of psychiatry to evaluations for legal purposes. Psychiatric evaluation of the patient is directed primarily to legal issues in which he is involved, and consultation is concerned primarily with the ends of the legal system, justice, rather than the therapeutic objectives of the medical system" (Pollack 1974). Pollack further distinguished forensic psychiatry from the broader category of psychiatry and law that he "considered the broad, general field in which psychiatric theories, concepts, principles, and practice are applied to any and all legal matters" (Pollack 1974). Although concerned with legal issues or legal patients, community psychiatric involvements in his opinion "lean toward the traditional ends of psychiatry, that is, toward healing or otherwise helping the patient."

Similar distinctions have been made between forensic psychiatry and the legal regulation of psychiatry (Rosner 1985). Rosner believes forensic psychiatrists function outside of their role as physicians and that this is ethical so long as they make it clear to others that they are not the evaluee's personal physician. Rosner makes an analogy between the forensic psychiatric role and the psychiatrist bargaining with a car dealer, without considering the salesperson's interests.

In contrast, the philosopher Foot argues that forensic psychiatrists in their professional role are hired specifically because of their being psychiatrists, and therefore can be seen as retaining their professional responsibilities (Foot 1990). They are also clearly using psychiatric and medical skills when conducting a forensic psychiatric evaluation. Several contemporary forensic psychiatrists believe that society expects some retention of medical values when physicians participate in the legal system (Weinstock et al. 1990; Candilis et al. 2001; Weinstock 2015).

Diamond (1992) also thought that forensic psychiatrists should not blindly accept all legal ends in their professional role. Diamond believed that the forensic psychiatrist has a fiduciary responsibility to the legal system, i.e., doing what is best in terms of professional judgment rather than merely acceding to the demands of the evaluee, attorney, or any other interested party. In his opinion—much like a psychiatrist owes a fiduciary responsibility to a patient to do only that which the psychiatrist believes in his or her professional judgment is best, rather than merely doing what the patient demands—the relationship between psychiatry and the law should also be fiduciary. According to Diamond (1992), "the psychiatrist is no mere technician to be used by the law as the law sees fit, nor is the science, art, and definitions of psychiatry and psychology to be redefined and manipulated by the law as it wishes." In his opinion, the psychiatric expert should not merely deliver information without any regard for negative consequences.

Appelbaum (1997) bases the ethics of forensic psychiatry on the principles of truth telling, respect for persons, and promoting justice. Griffith (1998) proposes a narrative

approach that takes the power differential and cultural considerations into account and examines the narrative of individuals of the nondominant culture. Candilis and colleagues (2001) integrate these approaches with a robust conception of professional integrity. They favor principles infused with the historical narrative of medicine as a healing profession that includes traditional medical values and an individual's personal narrative. Candilis and colleagues (2001), Weinstock and colleagues (2001), and Weinstock (2015) consider the need to balance conflicting responsibilities. In the forensic context, Weinstock agrees the duty to the legal system is primary, but that it needs to be balanced by a secondary duty to the evaluee that in some situations can become the dominant consideration. Such a circumstance could require a forensic psychiatrist to withdraw from a case if ethical concerns preclude a search for truth.

AAPL has defined forensic psychiatry as follows (AAPL 2005):

> Forensic psychiatry is a subspecialty of psychiatry in which scientific and clinical expertise is applied to legal contexts involving civil, criminal, correctional, regulatory or legislative matters, and in specialized clinical consultations in areas such as risk assessment or employment. These guidelines apply to psychiatrists practicing in a forensic role.

Unlike previous versions, this definition does not take a position on the goals and values of forensic psychiatry. The definition lists the differing contexts and functions of a forensic psychiatrist with an emphasis on the legal context of forensic psychiatric practice. However, forensic psychiatry has generally come to include and encompass all the issues and functions at the interface of psychiatry and law, including the legal regulation of contexts surrounding psychiatric practice, as reviewed by this textbook.

Neither lawyers nor the courts should determine the guidelines and ethical principles of how forensic psychiatry is to be practiced. The courts can decide what is legal, but not what is professionally responsible or ethical for forensic psychiatry.

Ethical guidelines and requirements can and do sometimes exceed what the law demands. The psychiatric profession can consider unethical, and provide sanctions for, behavior the courts consider permissible. Although the AAPL guidelines are aspirational in the sense that they are not enforced per se, they can be enforced when they flush out the meaning of guidelines of the American Psychiatric Association (APA) or state medical boards. Most guidelines are not intrinsically aspirational and can be and sometimes are enforced if other organizations choose to do so (Candilis et al. 2014).

FORENSIC EVALUATIONS

An AAPL essential ethics guideline involves informing the evaluee in any forensic psychiatric interview of the limitations of confidentiality along with for whom and for what purpose the interview is being conducted. This requirement differs from a clinical evaluation performed for a patient's benefit in which confidentiality is expected and generally is maintained. However, even in the clinical setting, confidentiality limits should be explained when they appear potentially relevant. There may be some exceptions, however, in situations of serious suicidal or homicidal danger. In such scenarios, it may be important for the treating physician to hear this information without interrupting to advise on the limits of confidentiality in order to prevent actions that could result in serious bodily harm or death to the patient or a third party. Some may think the limits of confidentiality should always be explained at the outset of treatment, but a comprehensive list would be very long and unnecessarily frighten patients who are unlikely to ever encounter any such exceptions. Psychiatric ethics guidelines permit such discretion though psychologist guidelines do not (American Psychological Association 2010).

In conducting forensic evaluations, it is of crucial importance to acquire adequate data on which to base professional opinions. For example, in the criminal setting, not only the discovery information, but the evaluee's current and past psychiatric, medical, and other records, interviews of relevant parties, and/or access to information held by the prosecution in a criminal case or both sides in a civil case not included in the discovery information, may be important to arrive at a professional opinion. In such cases, the forensic psychiatrist should request this information. For the civil setting a similar set of data from both the plaintiff and defendant may be needed in order to perform an adequate evaluation.

Because of the legal purpose of the forensic interview, an evaluee has rational reasons to exaggerate, manufacture, or minimize symptoms; therefore, whenever possible there should be corroborating data for the evaluaee's self-report (see Chapter 74 on Malingering). Such data also should be obtained not only for a thorough but objective evaluation, but also to prepare for a potential cross-examination. A careful evaluation is necessary, and an adequate evaluation requires time. Superficial evaluations can miss pathology or contradictory data. Although AAPL's ethical guidelines eliminated the requirement of impartiality in 1995 as it was not realistically achievable, the AAPL guidelines retain the need to strive for objectivity. Striving for objectivity includes the need to search for data that might contradict the forensic psychiatrist's initial opinion, biases, or both. "Honesty" has been substituted for "impartiality" in AAPL's ethical guidelines.

Diamond (1956) called attention to the fact that seriously mentally disordered persons commonly deny their illness. Simulation of sanity can be just as great a problem as simulation of mental illness, though the forensic psychiatrist may be less likely to be alert to detect faking good (dissimulation) than faking bad (simulation). An evaluee's emotional need not to be thought crazy may outweigh his or her legal self-interest. Denial of mental illness also contributes to this and may not be intentional.

There is a clear risk in forensic psychiatry of confusing professional expertise with biases about moral issues or a biased choice of one of many interpretations of the legal criteria. To quote Pollack (1974), "in forensic psychiatry, the expert applies his material to social ends, all of which are intimately related to moral values." Because psychiatric material can be largely subjective, interwoven with social variables, and influenced by a variety of cultural factors, what is presented as psychiatric data and opinion may easily disguise and conceal underlying value judgments. Although forensic psychiatrists are experts in psychiatry, they are likely to be neither experts in morality nor experts in the meaning and intent of legal terms and judicial opinions.

ROLE OF THE FORENSIC PSYCHIATRIST

Pollack was a proponent of what has been the dominant approach in modern forensic psychiatry, at least in most theoretical discussions. Diamond, however, was a proponent of an alternative but equally legitimate approach that may in reality informally be the dominant position of forensic psychiatrists, at least as reflected in surveys (Weinstock et al. 1991). Most forensic psychiatrists do not see themselves as functioning totally outside of their medical and psychiatric roles. They use their medical and psychiatric skills and techniques in the forensic role. They also can be perceived as functioning in a medical role by those they evaluate despite any disclaimers and because they conduct a psychiatric assessment. Even if an evaluee understands the specific role of the forensic psychiatrist, slippage can occur with the evaluee coming to view the forensic psychiatrist in an increasing therapeutic role, especially if the psychiatrist is empathic. Forensic psychiatrists should be sensitive to slippage of the initial warning.

In order to illustrate the proper role of forensic psychiatrists, Diamond and Pollack's views will be contrasted. They both were highly respected contemporaries with many differing views who wrote extensively on this issue during the dawn of the modern era of forensic psychiatry. Their positions are still matters of contention today. Both Diamond and Pollack agreed that forensic psychiatry applies psychiatric theories and practices to people and their legal issues for legal purposes. However, they differed insofar as Pollack thought the ends are legal ends. Diamond thought forensic psychiatrists should retain their medical and psychiatric ends in the forensic role and work toward making the legal system more therapeutic and less vengeful. This concept has a legal counterpart in the concept of therapeutic jurisprudence (Stolle et al. 2000).

Pollack wanted the forensic psychiatrist to ascertain social policy considerations and try to determine the intent of the courts and legislators. He made this attempt in the common situations in which the legal criteria are unspecified, unclear, or ambiguous. Both Pollack and Diamond thought that forensic psychiatrists have an obligation to present and expose their reasoning so that a trier of fact could understand the basis for their opinion, detect any biases, and disagree if necessary. Pollack would not try to expand or modify a legal concept in his forensic psychiatric capacity. He would try to overcome biases, including what he considered the psychiatrist's usual "therapeutic bias." He would attempt to give an impartial objective opinion in his role as consultant to the legal system (Pollack 1974) and not participate in cases in which his bias was strong.

Although Diamond agreed that his reasoning should be exposed, in contrast, he would interpret ambiguities in the legal criteria to be consistent with the values of the medical profession, but would be totally honest about doing so. That strategy may be less effective today because appellate courts are more conservative.

Diamond, himself, chose to be an expert witness solely for the defense in criminal cases. However, he would only participate in cases in which an effort would be made by the defense attorney to present the whole psychiatric truth. In most cases, he would refuse to participate after being consulted, because he did not think an honest opinion would help the side that wanted to hire him, or he did not want to be part of a legal strategy that would hide relevant information. Although he wanted to help a defendant, truth and honesty were even higher values.

Diamond interpreted legal ambiguities in a manner consistent with his view of his fiduciary responsibility. Although he had a bias in favor of a defendant's welfare, he accepted the biases of others who favor law and order and the protection of society. However, in his opinion, honesty was crucial. Although few forensic psychiatrists would go so far as to never participate for the prosecution in any criminal case, many forensic psychiatrists agree with other aspects of Diamond's approach or share his concerns about not facilitating a death penalty sentence (Weinstock et al. 1992) or, in some special situations, assisting an organization or company they think has no redeeming social value (Weinstock 2015). Many evaluators care how their testimony will be used in death penalty or other cases. Other practitioners may have qualms about helping a killer avoid punishment.

Diamond considered impartiality and objectivity impossible (Diamond 1959) and thought that the honest forensic psychiatrist should acknowledge the absence of both. Even if forensic psychiatrists start out truly impartial, the desire to defend their opinions and have their team prevail turns forensic psychiatrists into biased adversaries as the case proceeds. Though some commentators state witnesses on the stand must do their best to impartially preserve the truth (Halleck et al. 1984), Diamond considered impartiality impossible even if witnesses are totally truthful from their own subjective standpoint. The truth can have many alternative perspectives. Katz (1992) recommends "disciplined subjectivity" as a more realistic goal instead of impartiality or objectivity. Honesty in Diamond's (1990) opinion is what separates the honest advocate from a "hired gun." Although the more scientific aspects of psychiatry might be relatively objective, much of psychiatry remains subjective. Furthermore, our interpretation of the legal issue and application of psychiatric data to it are especially subjective.

Despite these considerations, forensic psychiatrists frequently are asked to indicate how often they have testified for the different sides in a legal case. Federal courts require such disclosure, which can be problematic insomuch that the information obtained can be misleading. Sometimes, those who are found to testify equally for the prosecution and defense may create an illusion that this balance reflects lack of bias, when in reality it reflects extreme dishonesty. For example, "hired guns" make a record of testifying on both sides because they are willing to testify for whichever side pays their fee regardless of their actual opinion or the merits of the case. Claims of impartiality can reflect dishonesty or lack of self-insight. Alternatively, principled though biased professionals who testify primarily for one side can be honest. The U.S. Supreme Court in *Ake v. Oklahoma* (1985) recognized bias and even advocacy implicitly by stating that defendants in capital cases needed an expert to assist defense counsel.

Many forensic psychiatrists in civil cases testify primarily for the plaintiff or defense. Although most insurance companies wish to have an "independent" medical examiner to prevent their wasting resources on indefensible cases, that sometimes is not the case. Some forensic psychiatrists contend that a number of insurance companies do not want to hire forensic psychiatrists who ever have testified against them for the plaintiff's side, and choose not to take such cases for fear they will not be hired by these companies in the future. Additionally and more concerning, some forensic psychiatrists may distort their opinions in order to please the party hiring them. For example, some insurance companies regret issuing policies that have lost the company money. For example, they now may want not to pay legitimate claims for physician policies covering disability in a specific subspecialty (e.g., an anesthesiologist with a substance use disorder). Insurance companies might want a forensic psychiatrist to say that the only reason the anesthesiologist cannot practice the specialty is medical board prohibition when the reality is the main reason the physician should not practice anesthesiology is the ready access to drugs previously diverted for personal abuse. Hopefully, most forensic psychiatrists would not distort their opinion just to please the insurance company. Some who do may be "hired guns."

Testifying for one side only does not necessarily imply being a hired gun. Many who testify for only one side in such cases probably choose a side most consonant with their values or biases, and are probably essentially honest. Sometimes only one side refers cases. Honest testimony out of interest in the issues but with only minor or negligible biases usually leads to some record of testifying for both sides, even if not equally distributed. If doing work solely for one side for whatever reason, honest experts should find many cases with facts not supporting the side retaining them. Nonetheless, in spite of any unintended bias based on retention by one side or the other, AAPL's ethical guidelines hold that the forensic psychiatrist has an ethical obligation for honesty and to strive for objectivity.

Most forensic psychiatrists are unlikely to make the best case possible for unsupportable opinions. Honesty requires informing the hiring attorney as soon as possible if a review of all the materials does not support a helpful opinion. The attorney then can either drop the case or look for other experts who see the case differently. Making the best case for a side regardless of stronger contradictory facts is an approach appropriate and ethical for attorneys. However, this is a defining difference that highlights the contrast between the role of the attorney and the role of an expert witness, and legal and forensic psychiatric ethics. Unlike attorneys whose ethics permit distortions, supporting the use of any permissible tactic for their client so long as they do not lie, an expert witness takes an oath to "tell the whole truth." It is ethical to highlight and emphasize the strong parts of a case, though such emphasis should not lead to distortion to the level of confidence in an opinion or a denial of uncertainty despite pressures from attorneys to appear certain. The acceptable dividing line, however, sometimes is unclear. The legal system unfortunately facilitates a perception of a misleading level of certainty by calling a preponderance of evidence "reasonable medical certainty." The integrity of the psychiatric expert should prevent distorting a case in order to please an attorney.

Forensic psychiatrists can consult with attorneys about the forensic psychiatric merits of a case and strategy as well as provide expert testimony. Although no oath is taken when consulting with attorneys, the primary reason to separate roles is it does not look good to a jury for the expert to then appear to be advocating for a particular result. But testifying experts can give advice to attorneys and advocate for their opinion.

General philosophies can represent preferences for how a specific forensic psychiatrist wishes to function, but they may have exceptions. Despite Pollack's philosophy, he himself refused to participate in capital cases after that of Sirhan Sirhan (who assassinated Senator Robert F. Kennedy) (Curran and Pollack 1985). He apparently agreed with Diamond that forensic psychiatrists should refuse to participate in cases in which they do not agree with the legal system's goals. More recently Weinstock (2015) shares this view. However, unlike Diamond and Weinstock, Pollack believed he needed to be prepared to support either side if he became involved in a case. Diamond believed he could support only one side, though only if he could do so with total honesty because total disclosure of the facts supported his position. Weinstock (2015) believes this applies only in some unusual situations in which secondary duties such as nonmaleficence overcome the primary forensic duty.

Unfortunately, not all forensic psychiatrists are as open and honest as Pollack and Diamond. They may intentionally create false impressions and a few may even be willing to be "hired guns" (Diamond 1990). They may make the best case possible for a weak opinion regardless of their actual findings and conclusions in order to be hired for this case and others by the attorney. Or they may be so committed to a cause that they will misrepresent the data to support their

cause. This role may be appropriate for an attorney, but not for an expert witness who, unlike an attorney, takes an oath to tell the whole truth and not present a one-sided version to help "win" the case as attorneys sometimes do.

An example of differing approaches and biases is shown in the contrasting interpretation by Pollack and Diamond of the *M'Naghten* insanity defense as used in California. Pollack's interpretation tended to favor the prosecution, while Diamond's clearly favored the defense. Pollack described social policy considerations as requiring that "knowing" the nature and quality of the act in an insanity defense is broader than a simplistic, atomistic, childish level of comprehension, but does not encompass the maximum breadth, scope, and maturity of fullest comprehension (Pollack 1974). Diamond, in contrast, interpreted "know" to mean appreciate, comprehend, or realize the act's full meaning. Some jurisdictions have adopted the word "appreciate" instead of "know" to indicate a broader view of the word "know."

Diamond opined that a literal interpretation of *M'Naghten* would either encourage perjury or force the psychiatrist to "become a puppet doctor, used by the law to further the primitive and vengeful goals demanded of our society." He thought that if a literal sense of "know" is employed, "just about almost every defendant, no matter how mentally ill, no matter how far advanced his psychosis, knows the difference between right and wrong in the literal sense" and the psychiatrist becomes an expeditor of the death penalty (Diamond 1961). Diamond preferred not to resort to semantics and to an arbitrary all-or-none insanity defense but preferred to focus on the *mens rea* defense of "diminished capacity." He played an important role in the development of this defense, and in this process changed the interpretation of the law. That defense later was substantially weakened primarily by returning to English common law definitions of terms like "premeditation" and "malice" in the current defense of "diminished actuality."

RESPONSIBILITIES OF THE FORENSIC PSYCHIATRIST

Controversy exists regarding to whom the forensic psychiatrist owes a duty. This problem in part is due to the fact that a traditional doctor–patient relationship does not apply. Stone (1992) states that psychiatry enters an ethical morass when it leaves the clinical situation, such as in managed care or in forensic psychiatry. According to Appelbaum (1990, 1997), forensic psychiatrists lose the primacy of the duties of beneficence and nonmaleficence owed by treating physicians to their patients. Instead the duties of truth and respect for persons, and the goal of justice achieve primacy in the legal system. Stone (1984) does not believe "truth" solves forensic psychiatry's problems such as the good clinician seducing a patient into false trust. Surveys of forensic psychiatrists indicate that an overwhelming majority still believe that traditional medical values play a role in the functioning of forensic psychiatrists (Weinstock et al. 1991). Despite the survey findings, controversy exists in the profession regarding this issue (Weinstock et al. 1990; Weinstock 2015). In modern times, even treating psychiatrists owe a responsibility to society as well as to the patient, such as reporting suspected child and elder abuse. Most consistent with survey results, it is reasonable to view the forensic psychiatrist similar to the treating psychiatrist as having multiple agency responsibilities, such as to the courts, society, the retaining attorney, and the evaluee, regardless of who requests the psychiatric consultation.

The difference in responsibilities is probably best characterized as a difference in priority or primacy. That is, the forensic psychiatrist, unlike the treating psychiatrist, gives primacy to answering the legal question and specific forensic duties like truth and respect for persons (Appelbaum 1997). However, secondary medical responsibilities remain. These in some instances can be so important that they can become determinative of ethical action (Candilis et al. 2001; Weinstock 2001, 2015). In some death penalty roles, the conflict between primary forensic duties and secondary medical responsibilities most appropriately may require nonparticipation. Dialectical principlism (Weinstock 2015) presents as a method to determine the most ethical course of action for oneself.

Although controversy still exists, survey results best support a position of multiple agency and multiple responsibility for a forensic psychiatrist. Even though some forensic psychiatrists believe they owe a duty and responsibility only to the person who pays their fee if they make their role and allegiances clear at least once to an evaluee, survey results imply that this position may actually be held by only a minority of forensic psychiatrists. Furthermore, slippage of a warning may occur if the forensic psychiatrist is a good clinician who inspires trust. Although frequently claimed, it is unclear why a forensic psychiatrist should owe a duty solely to the person paying the fee when even treating psychiatrists do not have the luxury of such a simple, single allegiance. Thus, multiple responsibilities have become a part of all psychiatric practice.

It is important not to hold the profession of forensic psychiatry responsible for unpopular legal decisions that may result from many factors. Sometimes the decisions are unpopular but valid, or the judicial system may limit the evidence an expert is permitted to introduce. Unpopular insanity acquittals have led to changes in the law and undeserved negative press for forensic psychiatry. Sometimes forensic psychiatrists unfairly are blamed for problems presented by the adversary legal system and for the "battle of experts." Psychiatrists have legitimate differences of opinion. The "battle of experts" exists for all expert witnesses in all disciplines and is by no means unique to forensic psychiatry. Sometimes there is a risk of blaming the entire profession of forensic psychiatry when the public dislikes a decision or the testimony of a particular expert. Newspapers and politicians use such scapegoating for personal advantage. Sometimes the entire profession is blamed for the actions of a few "hired guns."

Stone (1984) expressed concern about the jury's confusion caused by a psychiatrist taking an oath to tell the whole truth yet in reality being expected by the legal system to make the best case possible for the retaining side. Stone proposes that psychiatrists be introduced in court as partisans similar to attorneys who take no oath. Stone argues that the rationalization that cross-examination will bring out the whole truth is self-deceptive, since such cross-examinations may never occur (e.g., pretrial settlement of the case). He is skeptical that forensic psychiatrists really tell the whole truth. Stone advocates honesty about what really is occurring. What is the "whole truth" is debatable, and the legal system limits how much of it can be told even if the forensic psychiatrist tries to do so. Additionally, Stone's criticisms apply to all expert witnesses and even the adversary system, and his recommendations show no sign of being adopted by any profession. Also controversial is the degree of the psychiatrist's obligation to clarify limits of his or her opinion (aside from any possible tactical advantage in doing so) or whether such clarification can be rationalized as left for cross-examination that may not occur or be done well, despite the admonition in the AAPL ethics guidelines to affirmatively state the limitations of an opinion if there is no personal examination. Katz (1992) considers acknowledgment of uncertainty as a crucial responsibility of the forensic psychiatrist.

PRESENT STATUS OF FORENSIC PSYCHIATRY

Weinstock (2015) has developed the approach of "dialectical principlism" as a method to analyze and resolve ethics dilemmas. It entails prioritizing duties according to role and then balancing them along with ethics principles and personal, societal, and cultural values.

Although controversy exists regarding some aspects of the proper role and responsibilities for forensic psychiatrists, many issues have found a general consensus in definitions and ethics guidelines. The AAPL ethics guidelines present an important ethical foundation. But those wanting to find the most ethical solution to a dilemma beyond minimum guidelines can use the method of dialectical principlism (Weinstock 2015). This method can help us determine the most ethical course of action for ourselves. It also can improve the public perception of, and credibility of, our field.

Forensic psychiatry fellowships teach the special knowledge necessary to apply psychiatry to legal issues. General residency training in psychiatry even supplemented with formal legal education is insufficient, because most law schools do not emphasize psychiatric issues or their application to the law. Specialized training is needed in forensic psychiatry covering an evolving and specialized body of knowledge, even for psychiatrists with law degrees.

Forensic psychiatry is a large subspecialty as evidenced by this textbook. The vastness of the knowledge base, both clinical and legal, creates challenges for the forensic psychiatrist to act responsibly. Claims of expertise in areas where the psychiatrist does not have special knowledge or training despite this specialization being relevant, can raise questions about whether general forensic psychiatrists should undertake evaluations in subspecialty areas. Cases involving children, the elderly, or psychosomatic problems are routinely seen by general psychiatrists and are not exclusive to those with specialized training. Questions remain whether this is acceptable practice if specialists are available.

Alternatively, it could be argued that any psychiatrist could do the assessment if sufficiently knowledgeable about the specific issues pertinent to the case. Careful evaluation of the relevant data is important considering the serious implications to the parties involved. A healthy skepticism regarding all the data supplied by either side of the legal conflict is necessary. Offering psychiatric–legal opinions on legal issues without trying to ascertain the jurisdictional legal criteria are two prime examples of irresponsible professional behavior. It is therefore incumbent on forensic psychiatrists to be informed about psychiatry, law, and ethics, in order to appropriately fulfil their professional roles and responsibilities. That is especially important when those without forensic training or expertise undertake a forensic evaluation, but also applies when those with forensic training undertake a case without relevant psychiatric expertise or knowledge of the legal criteria in the relevant jurisdiction.

When we perform our roles properly, forensic psychiatrists can assist the legal system in its effort to foster justice as well as promote a favorable impression of ourselves and our profession. (See Chapter 8, Forensic Psychiatric Ethics, for additional exploration of these topics.)

History of forensic psychiatry

MARVIN THOMAS PROSONO

An inquiry into the formal recognition of forensic psychiatry as a medical subspecialty places heavy demands on historical reconstruction. It is not sufficient to engage the history of forensic psychiatry simply as a subtext of the greater history of psychiatry. This approach has been taken by most of the standard histories of psychiatry (Alexander and Selesnick 1966; Zilboorg 1967; Ackerknecht 1968), which portray psychiatry either as foreordained by the inevitable march of science or as crusading against the inertia of entrenched superstition and ignorance. Medical specialties have generally evolved alongside the natural sciences, although psychiatry has not precisely followed this path making its history more difficult to reconstruct (Marx 1970, 595). The history of forensic psychiatry can be traced through the dual emergence of psychiatric and legal discourse and practice as these have mutually developed and intersected over the centuries. This chapter follows the history of that intersection through the ancient, medieval, and modem periods after first considering the nature of the complex intellectual problems involved in constructing such a history.

Drawing a boundary around the activity of forensic psychiatrists is problematic because all psychiatric activity may contain an element of "forensicity." Park Dietz provided the following quote in regard to this concept of "forensicity."* It is an even greater challenge to trace back the activities preceding those now systematically performed by forensic psychiatrists. Psychiatry as a medical specialty did not exist much before the late eighteenth or early nineteenth century, and the widespread employment of physician/experts in courts of law in the West does not have a pedigree that is much older. Foucault (1972, 179) has commented that what preceded psychiatry could not be characterized as a discipline but rather was a "discursive practice" that consisted of a commentary on various physical and mental afflictions as understood at the time.

In sociological terms, the forensic psychiatrist is a medical professional called upon to participate in the establishment of legal decisions, particularly those decisions affecting the status of persons, further validating the decision-making process with their scientific and professional credentials (Prosono 1990). The task of the social historian is to construct an account of this form of social action and the concerns that gave rise to it; however, there are a number of technical obstacles that preclude any perfect reconstruction of the past (Mead 1980). Continuities, discontinuities, appearances, disappearances and reappearances, things maintained, modified, or abandoned (Foucault 1972) characterize a "discursive practice" such as that of forensic psychiatry and its predecessors in social action.

Two concerns are implicitly embedded in this history. First, there are the ancient and enduring problems of human motivation and intention. All legal systems have had to grapple with the problem of deciding competency and accountability. Second, in order to decide such questions there must be decision makers. In courts of law, judges and juries are the ultimate decision makers: judges deciding questions of law; juries, in the Anglo-American system of jurisprudence, deciding questions of fact. Matters of insanity or incompetence have routinely been described as questions of fact, with decision makers assisted, especially in modem contexts, by a highly professionalized group of experts. The history of forensic psychiatry is, in effect, the history of the intersection of the enduring legal and social problems of establishing competency and imputing responsibility, and both the professionalization of medicine and the specialization of psychiatry.†

ANCIENT PERIOD

Imhotep (circa 3000 BC), grand vizier and chief architect to the Egyptian Pharaoh Djoser, was "the first great man combining the sciences of law and medicine; he might, if you

* [I]n an era in which virtually every psychiatrist must take cognizance of certain medicolegal principles, an argument could be made that "forensicity" is a continuous variable distributed unevenly over the entire population of psychiatrists (Dietz 1978, 13).

† Appendix 3.1 summarizes the important dates and events in the evolution of forensic psychiatry.

wish, be described as the first medicolegal expert" (Smith 1951, 600). In Imhotep we find the undifferentiated roles of priest/physician/statesman/architect, although we should be wary about placing too much credence in the accomplishments of a figure who may be entirely a myth.

According to some authorities, ancient Babylonia provides us with evidence of the first murder trial and the first expert witness, in that case a midwife (Smith 1951, 600; Ackerknecht 1976, 1225). One of the first instances of the consideration of intent in the weighing of personal responsibility is found in the scriptures of the ancient Hebrews.* Deuteronomy 19:1–13 describes the logic for establishing "refuge cities" in which someone who had killed through sheer accident would be safe from capture by avenging relatives. The ancient Hebrew law understood the status of an act as determined by the intent of the actor. Thus, the notion of an evil mind entered into Western law (see Platt and Diamond 1966). The importance of intention for judging human action was already evident in the Babylonian legal system as set forth in the Code of Hammurabi, although this system of law was especially harsh, death being the sole punishment for violations of law. Such an approach can be found in much primitive law, which takes little or no account of an actor's intention. Kelsen has termed this "absolute responsibility (liability)" (Kelsen 1946, 65).

The ancient Greeks left the resolution of many conflicts to "private law," meaning that the parties to a dispute would be left to decide it among themselves. There was little need or opportunity for the rendering of expert or forensic opinion, other than isolated instances such as a physician substantiating the pre-existence of a defect in a slave who had been sold. When questions of mental competence arose, there is no evidence that physicians were used as experts among the Greeks in any modern sense (Rosen 1968, 136).

The Greek philosopher Plato saw the human soul as divided between the rational and irrational, the rational soul distinguishing human beings from lower or animal nature (Zilboorg 1967, 52). Because human beings are free to choose, more severe punishments should be imposed for those "harms committed with some degree of calculation" (Platt and Diamond 1966, 1229). Plato's great disciple, Aristotle, recognized the importance of knowledge in the imputation of responsibility: "A person is morally responsible if, with knowledge of the circumstances and in the absence of external compulsion, he deliberately chooses to commit a specific act" (cited in Platt and Diamond 1966, 1229).

These early approaches have had a significant impact on all subsequent discussions of the problem of responsibility. They presage the tension among those who would excuse the insane from responsibility for criminal acts only when there is evidence of a total loss of reason (analogous to the behavior of a "wild beast"), those who would allow such excuse when the only apparent mental impairment is a cognitive one, and others who ask whether there existed "an irresistible impulse" or whether the act was a "product" of the disease or impairment.

The heritage of Western medicine derives from Greece, and Hippocrates is considered the father of that medical tradition. He insisted that diseases were of natural origin and could be both understood and treated as manifestations of the natural order (Ackerknecht 1968, 10). Possessing a "clinical intuition," Hippocrates suggested that various physical diseases alleviated "madness" or "mania," anticipating by some 2300 years the malarial treatment of mental disease resulting from syphilis (Zilboorg 1967, 48).

Ptolemaic and Roman Egypt are of interest because of the existence of a *demosios iatros*, or public physician (Amundsen and Ferngren 1978, 338 et seq.). Although certain kinds of knowledge were exploited by Ptolemaic courts such as the expert opinion of land surveyors, physicians were not summoned to court to give expert opinion (Amundsen and Ferngren 1978, 340).

Among ancient legal systems, Roman law was certainly the most comprehensive and sophisticated. Like its Greek predecessor, Roman legal process did not employ physicians as experts (Sesto 1956, 33), although midwives, land surveyors (*agrimensores*), and handwriting experts were used in a forensic capacity (Amundsen and Ferngren 1979, 48). A iudex, or judge, had very wide discretion in gathering and considering evidence and took the counsel of *adsessores*, who were wise men learned in jurisprudence; however, there is no evidence that either on a regular or exceptional basis were *adsessores* members of professions whose knowledge could help decide questions of fact (Amundsen and Ferngren 1979, 46).†

Yet Roman law did recognize that those who committed acts without malicious intent should not be held accountable for those acts. The *Twelve Tables*, one of the earliest Roman codifications, made provision for a system of guardianship of the insane, usually placing the person and his or her possessions under the care of paternal relatives. The *Lex Aquila* in the third century BC provided: "[A] man who, without negligence or malice, but by some accident, causes damage, goes unpunished" (quoted in Platt and Diamond 1966, 1230). Under the *Lex Cornelia* (first century BC), children, because of the innocence of their intentions, and the insane, because of the nature of their misfortune, were excused from punishment (Platt and Diamond 1966, 1230).

* Platt and Diamond trace the "modern law of criminal responsibility" to the conflicting meanings given to the phrase "knowledge of good and evil," which figure in the Book of Genesis and the story of Adam and Eve and the forbidden fruit. The phrase "knowledge of good and evil" has been interpreted to mean perfect wisdom as well as moral capacity, and the ensuing confusion has been preserved, according to these authors, in modem law (Platt and Diamond 1966, 1227 et seq.).

† In cases where a curator is to be appointed to discharge the affairs of one who is considered insane, the praetor [a public official] is urged to investigate the case most thoroughly "since many people feign madness or insanity" so that they may evade their civil obligations (citing Digesta 27, 10, 6 [Ulpian]) (Amundsen and Ferngren 1978, 43).

On the subject of the insane, Roman law deals primarily with questions of guardianship and is not plagued by the almost single-minded concern with criminality one finds in modern sources. The question of intention, while important in the ancient literature, is overshadowed by issues of custody, protection, and status. This difference in emphasis flows from the approach that the Romans took toward the behavior of those who were deemed deviant or insane. The sometimes devastating result of their irrational behavior could be remitted by compensation to the victims paid by the guardian of the insane. Payment of money could act as a remedy even in a case of murder if the relatives of the victim (or the owner of the victim, in the case of a slave) would agree to such payment instead of some form of physical retribution. Roman law was not exceptional in this respect, somewhat the same kind of system obtaining in Anglo-Saxon and Danish England (Walker 1968).

Roman medicine reached its apogee in the person of Galen (AD 130–200) who, like Hippocrates, was a scientific positivist, rejecting soothsayers in favor of anatomists (Zilboorg 1967 [1941], 87). He saw the brain as the seat of thought, but posited two irrational souls, one in the heart and the other in the liver. Unfortunately, Galen became enshrined as a medical authority even though most of the dissections he performed were limited to pigs and dogs. Many medical riddles (such as the circulation of the blood) remained unsolved for over 1300 years until the authority of Galen was overthrown.

MEDIEVAL PERIOD

The Middle Ages (approximately the sixth through the sixteenth centuries) was a period of scientific retrenchment during which the traditions of Rome and theology of Christianity held sway throughout most of Europe. In AD 528 the Emperor Justinian ordered a review and codification of the enormous corpus of Roman legislation (Sandars 1970). The Code of Justinian, or the *Corpus Iuris Civilis*[*] (distinguishing it from canon or church law), made provision for the insane. Likened to one "absent, asleep or even dead," a person who became insane was protected from loss of property or position but was not considered capable of making a will, transacting any business, or held responsible for wrongdoing. Roman law followed the principle that "an insane person, like an infant not yet capable of understanding, usually before the age of 7 or 8, was incapable of malicious intent and the will to insult" (Van Ommeren 1961, 6).

The Roman Catholic Church, once established in Europe, relied on Roman law to answer many practical questions relating to insanity. How was matrimonial consent affected by insanity? Could the insane receive the sacraments of the church? Could a priest who became insane continue in his role? Should divorce be permitted if one of the partners became insane? How could it be determined that insanity was not being feigned in order to obtain a divorce? Secular authorities also had to contend with similarly difficult questions. How was it possible to detect a lawbreaker who feigned madness to avoid punishment? What were the rights of the madman who was in remission? Who would act as guardian to such a person? Two questions arise in any historical consideration of forensic psychiatry: How was it decided that any particular individual was mad or insane—that is, how was insanity recognized, and who was given the responsibility of determining the presence of insanity when it became an issue? No evidence seems to exist demonstrating that physicians were used as experts in the resolution of any of these questions during the medieval period.

The Italian city of Bologna may have been the first to establish a system of medical expertise that was used in what we would call criminal investigation (Simili 1973).[†] In Germany, the medieval city of Freiburg im Breisgau gave barbers/surgeons the responsibility of playing a forensic role at a time when academic medicine remained aloof from the problems of the mundane world (Volk and Warlo 1973). In their research, Volk and Warlo (1973, 101) found that "scientific forensic medicine was preceded for centuries by an empirical prescientific form that was motivated by the practical demands of the courts" but that before the appearance of Paolo Zacchia[‡] medical experts had not been utilized by courts. The ruling councils of fourteenth–century Venice relied on the *Corpus Iuris Civilis* (or the traditions of the Roman law) when faced with the problem of excusing behavior because of insanity. Once again we find that physicians did not assist the decision makers. Although physicians were called upon to testify concerning physical elements in a crime, they were not asked to testify when insanity was the issue. "This is not surprising. Insanity was

[*] *The Institutes of Justinian*, with English introduction, translation, and notes by the late Thomas Collett Sandars, M.A. 1970 (originally published 1922).

[†] Bologna is by no means the only one of the medieval Italian cities that incorporated into their laws detailed rules for medical experts. Such rules are also found, e.g., in the city statutes of Padua (1316), Genoa (14th century), Mirandola (1386), Bassano (1389), Florence (1415), Verona (1450), Brescia (1470), Milan (1840), Ferrara (1506), Genoa and Urbino (1556). These cities that played such a tremendous role in the genesis of modern economics. Political thought and art, must therefore also be regarded as among the most influential factors in the establishment of legal medicine (Ackerknecht in Burns 1977, 251).

[‡] The first complete edition of Paolo Zacchia's monumental work [Questiones MedicoLegales] was printed in 1654 in Rome. At that time the author was Proto medicus of the Papal State and medical advisor of the Rota, the High Court of the Roman Catholic Church (Karplus 1973, 125). This work of Zacchia's was considered the finest exposition and synthesis of medicolegal questions for many years after its writing and illustrates the sophistication that had developed in medicolegal thinking by the middle of the seventeenth century. [Paolo Zacchia] … may be rightly considered the founder of the medical jurisprudence of insanity (Zilboorg 1944, 508).

traditionally a community judgment, not a medical one" (Ruggiero 1982, 111).

In England, tests of legal insanity were developed and became part of the legal tradition of the common law. Henry de Bracton was an early and formative influence on the development of these tests. Occupying the position of chief justiciary of the highest English court, and author of one of the first substantial treatises on English law, *On the Laws and Customs of England*[*] (ca. 1256), Bracton has been identified with the "wild beast test" (Bracton, Henry de. 1977). This legal test of insanity demanded that in order for the insane to avoid criminal responsibility, a kind of fury or wildness must characterize the individual or the act. Platt and Diamond (1965), however, have demonstrated that Bracton's use of the concept of wild beast (brutus) was not in any way intended to compare the insane with wild beasts but was making the point that the insane, like animals, were not capable of forming the requisite intent to commit crime, much as a child would be incapable of forming such intent. When a decision on the insanity of an accused was an issue in an English criminal proceeding, the matter was given over to the judgment of the king. A royal pardon could be sought to release the insane from responsibility, a procedure also used to excuse those who killed by accident or in self-defense (Walker 1968, vol. 1, 24).

In England, the statute known as *Praerogativa Regis*[†] drew an important distinction between those who were termed "natural fools," congenitally abnormal, and those who were "*non compos mentis*," or whose symptoms of illness appeared after birth. The condition "*non compos mentis*" included a wide range of psychiatric disorders and, unlike that of "natural fool," was amenable to temporary or even permanent recovery (Neugebauer 1978, 159).[‡] How was it decided and by whom that an individual fell into one or another of these categories? Juries known as inquisitions were established to examine persons who might fall within the terms of the statute. The Court of Chancery empowered the sheriff and other public officials to make an investigation not only into the mental status of questionable persons but also the possessions and property they held. Like the pattern in the rest of medieval Europe, physicians were not involved in these determinations; a finding of incompetence or congenital insanity was in medieval England (as it was in medieval Venice) a "community judgment" (Neugebauer 1978).

One of the darker aspects of this "community judgment" during the medieval period was the practice of witch-hunting. From the fifteenth through the seventeenth centuries, thousands upon thousands of persons were tried on the charge of practicing witchcraft. The *Malleus Maleficarum* (or *Witches' Hammer)* written by two Dominican friars, Sprenger and Kraemer, set out the argument for the existence of witches, the manner by which they could be identified, and the procedures for properly trying them. A noteworthy appearance of a physician as an expert in an English court was made by Sir Thomas Browne (Finch 1950). Browne, author of the *Religio Medici*, a book of religious contemplation, participated in the witchcraft trial of two women in 1664 at Bury St. Edmonds, testifying that the devil might work through the madness of the women; thus, Browne appeared to support the independent existence of witchcraft and madness simultaneously.[§]

The physician Johann Weyer (1515–1588), possibly the first physician to devote the major part of his professional attention to psychiatric illnesses, is viewed by many as the voice of reason standing against the spirit of the time (Diamond 1961; Alexander and Selesnick 1966; Zilboorg 1967; Mora 1991). Alternatively, the witchcraft trials are portrayed by some as the true forerunner of the law/psychiatry interface. The psychiatrist Thomas Szasz (1920–2012) made a widely publicized career characterizing psychiatry as a modem version of witch-hunting. Although Szasz credited Weyer with recognizing that witchcraft was too often used as a diagnosis for what otherwise must have been madness, Szasz criticized Weyer for his belief in the existence of witches (Szasz 1970). For Szasz, however humane their motives may be, physicians who participate in the legal process assist in bringing medicine into the service of the law and of the forces of social control (see also Szasz 1974).

MODERN PERIOD

One commentator has traced the origins of modern forensic medicine to 1507 and the penal code drawn up by the Bishop of Bamberg, leading to the requirement placed in the

[*] Bracton, Henry de. 1977. *De Legibus et Consuetudinibus Angliae. On the Laws and Customs of England*, 4 vols. Translated with revisions and notes by Samuel E. Thorne. Cambridge, MA: Harvard University Press.

[†] The king's right is distinctly stated in the document known as Praerogativa Regis, which we believe to come from the early years of Edward 1 (1272-1307). The same document seems to be the oldest that gives us any clear information about a wardship of lunatics. The king is to provide that the lunatic and his family are properly maintained out of the income of his estate, and the residue is to be handed over to him upon his restoration to sanity, or, should he die without having recovered his wits, is to be administered by the ordinary for the good of his soul; but the kings is to make nothing to his own use (Pollack and Maitland 1968, 481).

[‡] "Whether a man was an idiot or a madman was a matter of local knowledge, and they [the petty jury] were therefore the obvious people to ask [concerning the mental state of an accused]" (Walker 1968, 24). In the seventeenth century, Lord Coke in Beverley's Case, 4 Co. 123b, 76 Eng. Rep. 1118 (K.B. 1603), made further clarifications to the distinctions between "idiots" or natural fools and "lunatics" and generally summarized the laws of England regarding insanity to his time (Brakel and Ruck 1971, 2-3).

[§] Some biographers of Browne, asserting that his testimony led to the convictions, have deplored his part in the proceedings (Finch 1950, 215).

Constituto Carolina of the Emperor Charles V that "required evidence of medical men in all cases where their testimony could enlighten the judge or assist investigation in such cases as personal injury, murder and pretended pregnancy" (Gerber 1961, 197). Erwin Ackerknecht finds the first reference to the medical expert in the courts of Paris of 1511 (Eigen 1985, vol. 2, 38). Whichever may be the case, the beginning of the sixteenth century apparently marks the recognition by legal authorities that forensic medical expertise was not only useful but indispensable.

What characterizes the transition to the modem period is the evolution of medical and legal theories concerning the behavior of the insane, the tests through which insanity has come to be recognized, and methods for the treatment of psychiatric illnesses. Older humoral or demonological theories were abandoned (sometimes without clear replacement), the commonsense tests for idiocy or lunacy were set aside, and the treatment accorded those defined as mad or lunatic changed from family guardianship to care in an asylum and then to maintenance on psychoactive medication.

Medical men slowly expanded on the distinctions made by the *Praerogativa Regis* between those born natural fools and those who became mentally impaired after birth. Thomas Willis (1621–1675) produced his own taxonomy of mental disorders, one of the most significant of which was melancholia, because the delusions under which a melancholic labored might be transitory. Willis distinguished between a "universal type" of melancholia in which the affliction affected all aspects of mental process and a "particular type" that would leave the judgment of an individual unaffected except in one or two areas (Jackson 1983, 176).

Matthew Hale (1609–1676), an English jurist who ultimately became lord chief justice and authored the *History of the Pleas of the* Crown (first published posthumously in 1736), may have been the first to use the term "partial insanity," a concept close to Willis' "particular type." In contrast to what he saw as "partial insanity," under which category he placed melancholia, Hale posited a "perfect madness" or "total alienation of the mind." Such a distinction was particularly significant because melancholia was a frequent basis for allegations of insanity (Jackson 1983, 173). Hale believed that it was an individual's state of mind and not the nature of his or her acts that was important in determining whether legal insanity could be used as a criminal defense (Mora 1976, 1419). In so positing, Hale was merely reiterating the logic of the English law commentators Bracton (d. 1268) and Coke (1552–1634), both of whom recognized that in order for a crime to exist there needed to be a *mens rea*, or an evil mind or guilty intent, along with an *actus* reus, or evil deed (Hermann 1983). Coke was of the opinion that the ends of punishment were not served by inflicting it upon those who were incapable of reason or understanding because such punishment could not serve as an example to others (Platt and Diamond 1965, 359; Blackstone 1979, vol. 4, 25).

The various tests of insanity to determine the presence or absence of an evil mind or criminal intent in Anglo-American law evolved through a series of important criminal cases beginning in the eighteenth century.* One of the first of those cases was *Rex v. Arnold*, 16 How. St. Tr. 695 (1724), Judge Robert Tracy presiding. Edward Arnold was tried for the attempted murder of Lord Onslow. The case has been interpreted as a precedent for the "wild beast test" in that "in order to be excused from criminal responsibility as insane, the accused must not know what he is doing, 'no more than an infant, a brute, or a wild beast'" (Judge Tracy quoted in Hermann 1983); however, it is clear that there are many different tests embedded in the instructions that Judge Tracy gave to the jury, such as a test of abstract moral judgment ("distinguish between good and evil").

"The trial of Earl Ferrers in 1760 marks the first recorded instance of 'psychiatric' testimony offered in the criminal trial" (Eigen 1985, vol. 2, 37). In a fit of rage, the Earl had shot and killed his steward, *Rex v. Ferrers,* How. St. Tr. 886 (1760). Dr. John Monro, physician superintendent of Bethlem (commonly known as Bedlam), testified as an expert witness. Dr. Monro was examined by the accused Earl Ferrers himself, who conducted his own defense in accordance with the English law of the time. The Earl was left in the difficult position of having to prove his own insanity; however, he conducted so sagacious a defense that his plea was not believed and he was found guilty and executed.

The standard of a total deprivation of reason was successfully challenged in 1800 in the case of *Rex v. Hadfield* (1800) 27 St. Tr. 1281. Hadfield had been a soldier attached to the Duke of York in the last years of the eighteenth century. While fighting, he had sustained severe head wounds, which led to his discharge from the army and resulted in permanent insanity punctuated by delusions of the world's imminent end and his role as its savior. To accomplish the world's salvation, Hadfield attempted to assassinate King George Ill so that he, himself, would be executed and thus save the world through his martyrdom. "Hadfield used a firearm, and came within a few inches of wounding, if not killing, George III" (Walker 1968, 74). Hadfield was disarmed, seized, and ultimately brought to trial. Unlike the unfortunate Earl Ferrers, Hadfield had counsel and was represented by the superlative jurist Thomas Erskine who managed to win an acquittal. Erskine recast the insanity defense in terms of disease process, a shift from the older insistence on tests of cognitive understanding or moral knowledge. It was no longer only the presence or absence of reason, but the presence of delusion or a deranged state of mind, which the jury was to take into account (Quen 1968, 45).

* It should be noted that the English common law tradition is known for its reliance on the precedent created by case law. Other European traditions that follow Roman or civil law (or variants of the Napoleonic code) do not assign the same importance to the precedents set by judicial decision-making in any particular case. Rather, statutes set out the law and judges (and less often juries) are bound only by the statute or code law and not by what other judges have determined to be the law in similar cases already decided.

> *Delusion,* therefore, where there is no frenzy or raving madness, is the true character of insanity; and where it cannot be predicated of a man standing for life or death for a crime, he ought not, in my opinion, to be acquitted … I must convince you, not only that the unhappy prisoner was a lunatic, within my own definition of lunacy, but that the act in question was the *immediate, unqualified offspring of the disease* … to deliver a lunatic from responsibility to *criminal* justice, above all, in a case of such atrocity as the present, the relation between the disease and the act should be apparent. (Thomas Erskine quoted in Hunter and Macalpine 1963, 571)

In 1812, John Bellingham was executed for the murder of Spencer Percevale, first lord of the Treasury and chancellor of the Exchequer. Although an insanity defense was raised, the decision in Hadfield's case was ignored and a knowledge of right and wrong test was employed. In 1840, Edward Oxford (*R. v. Oxford* [1840] 9 C.&P. 525) attempted to assassinate Queen Victoria. His subsequent insanity plea was successful. The Bellingham decision (*R. v. Bellingham* [1812] O.B.S.P. case 433) was explicitly disclaimed. "Lord Chief Justice Denman reaffirmed [in the Oxford decision] the primacy of the question of the determining or responsible factor for the act: the disease or the individual?" (Quen 1968, 46). A pattern seems to emerge from the eighteenth- and nineteenth-century cases: those who succeed in the commission of crime fail in their insanity plea; those who attempt a crime and fail, succeed in their insanity plea.

The case that definitely breaks this pattern, if there is a pattern, and establishes a rule that has been maintained by most American jurisdictions until the present day, is M'Naghten's case, 10 Cl & Fin. 200, 8 Engl. Rep. 718 (1843). Daniel M'Naghten, believing the man he shot in the back was Sir Robert Peel, the British prime minister, mistakenly assassinated Edward Drummond, private secretary to Peel. M'Naghten suffered from an elaborate set of delusions involving his persecution by the British government and the Vatican, among others. The ensuing trial is noteworthy for the number of physicians who were called as expert witnesses (nine in all), although two did not examine M'Naghten. They opined that no doubt existed as to his insanity even though M'Naghten might have been able to conduct his life along rational lines and understand the difference between right and wrong.

M'Naghten was found not guilty by reason of insanity after the case had been stopped by the judges. The two physicians called by the prosecution, although they had interviewed M'Naghten, never appeared or testified at the trial. Two of the defense experts (Winslow and Philips), although they never met M'Naghten and knew him solely by observing him in court, testified that he was insane, agreeing with the opinion of their colleagues appearing for the defense. On the strength of the medical testimony, Judge Tindal stopped the trial and charged the jury that returned with a verdict of not guilty by reason of insanity. This decision left Queen Victoria, her government, and the public in a state of uneasiness over the relatively undefined nature of that mental condition that would permit an insanity plea to succeed.

After the trial, the chancellor of the House of Lords addressed the House on the law of England regarding the responsibility of the insane and offered to call a convention of English judges. Three months later 15 judges of the Queen's Bench assembled for the purpose of clarifying the law (Quen 1968, 48). To these judges, the House of Lords addressed five questions. In part, the answers they gave to these questions have come to be called the M'Naghten Rules. These rules are still utilized in many jurisdictions in the United States. (For a discussion of current insanity tests, see Part 3, "Forensic Evaluation and Treatment in the Criminal Justice System.") Probably the most significant part of these rules for the further development of forensic psychiatry is that found in the answers to the second and third questions. These questions sought guidance on the instructions to be given to a jury and the terms into which these instructions should be cast:

> That the jury ought to be told in all cases that every man is presumed to be sane, and to possess a sufficient degree of reason to be responsible for his crimes, until the contrary be proved to their satisfaction; and that to establish a defense on the ground of insanity, *it must be clearly proved that, at the time of committing of the act, the party accused was labouring [sic] under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing, or, if he did know it, that he did not know what he was doing was wrong.* [Emphasis added] (Trial of Daniel M'Naughton, 1843 In: *Modern State Trials.* Revised by William C. Townsend, 1850, quoted in Hunter and Macalpine 1963, 921)

Besides establishing and limiting the legal conditions under which psychiatric expert witnesses would have to testify (and under which they testify to this day in many English-speaking jurisdictions), the decision in this case and the answers to the subsequent questions reveal an interesting and unexpected influence. If the *M'Naghten* case can be seen as an essential ratification of the presence of physicians in courts as experts on insanity, that ratification was achieved in no small part by the work of an American physician, Isaac Ray.

FORENSIC PSYCHIATRY IN THE UNITED STATES

The legal treatment of the insane in colonial America was consistent with the treatment they received during most of European history. Determinations of insanity continued to be made by civil authorities, not by physicians (Deutsch 1949, 40; see also Grob 1973). Compared with the growth of mental

asylums in Europe, American institutions devoted to the care and treatment of the mentally ill arose slowly and needed theoretical justifications from abroad. Based somewhat on its English predecessor, Bethlem (also known as Bethlehem or Bedlam), the Pennsylvania hospital, was opened in 1752.* Benjamin Franklin was among the men who founded it, and they had as one of their objectives the admittance of mental patients (Dain 1976, 1182). In a petition drawn up by Franklin for the provincial Assembly in 1751, he states:

> That with the Numbers of People, the number of Persons distempered in Mind and deprived of their rational Faculties, hath greatly increased in this Province.
>
> That some of them going at large are a Terror to their neighbors, who are daily apprehensive of the Violences they may commit …
>
> That few or none of them are so sensible of their Condition, as to submit voluntarily to treatment that their respective Cases requires, and therefore continue in the same deplorable state during their Lives; whereas it has been found, by the existence of many Years, that above two Thirds of the Mad People received into Bethlehem Hospital, and there treated properly, have been cured. (Franklin, quoted in Deutsch 1949, 59)

By 1844 a large network of public and private asylums existed in the United States.† In that year, 13 superintendents of mental asylums founded the Association of Medical Superintendents of American Institutions for the Insane (AMSAII). One of the founding members of that association was Isaac Ray, who became the superintendent of Maine Insane Hospital in 1841 and later superintendent of the Butler Hospital in Providence, Rhode Island. At age 31, Ray wrote A *Treatise on the Medical Jurisprudence of Insanity* (1838),‡ one of the first systematic studies in English of the law/psychiatry interface.

The element in Ray's thinking that seems to have had the most profound effect on developments both within law and psychiatry is the notion of "moral insanity," a concept introduced by James Cowles Prichard, nineteenth-century English physician and scholar.§ Ray was critical of the English tests of insanity because they were too concerned with cognitive function, ignoring the role of emotion and the impact of mental disease on "moral" functioning:

> In legal contexts the term "moral insanity" implied an inability to conform to the moral dictates of society—as a consequence of disease, not depravity, and despite the absence of traditionally accepted signs of mental disturbance. The morally insane offender might seem to be quite rational in conversation, even intelligent, be able to solve problems and be subject to no delusions or sensory misconceptions—yet still be mentally ill. (Rosenberg 1968, 68)

Ray's treatise followed the work of the reformers Vincenzo Chiarugi, Philippe Pinel, and William Tuke, who through religious or ideological optimism attempted to cure the insane by either softening the atmosphere of the mental institution (Pinel supposedly struck off their chains) or taking them out of destructive environments into the countryside. "Moral treatment" consisted of kindness, understanding, and what resembled a type of behavior modification therapy.

By the middle of the nineteenth century, the notion of moral insanity gained additional support among those who followed the phrenologists Gall and Spurzheim. These men had attempted to connect particular mental faculties to particular sites within the brain. Thus, following on this logic, it would be possible for a person to be totally lucid and in apprehension of the difference between right and wrong and yet commit felonious acts because the part of the brain in charge of moral control might be diseased. During the trial of Charles Guiteau, the assassin of President Garfield, discussed later in this chapter, the various psychiatric and neurological experts who appeared debated whether "moral insanity" was a viable medical notion.

For alienists (as early psychiatrists were known) the debate over the issue of moral insanity had a significant impact. The work Ray had done affected the outcome of the M'Naghten trial and became an influence on English and American legal usage:

> Alexander Cockburn, counsel for the defense [M'Naghten's defense], followed the lead of Lord Erskine [defense counsel in Hadfield's case] and attempted to establish a more flexible test

* The idea of the Pennsylvania Hospital originated with Dr. Thomas Bond, a man who had been disowned by the Friends in 1742 for taking an oath. Having visited England later, he was impressed with the care provided the mentally ill at Bethlehem Hospital (Deutsch 1949, 17).

† The following is a list of the location of some of the early American mental hospitals and their dates of establishment: Philadelphia, Pennsylvania. 1752; Williamsburg, Virginia (first state-supported mental asylum), 1774; New York Hospital, New York, 1791; Frankford, Pennsylvania, 1817; Boston, Massachusetts, 1818; Hartford, Connecticut, 1824; Lexington, Kentucky, 1824.

‡ Five years before M'Naghten's trial, an American doctor, Isaac Ray, had published what was to become one of the most influential books of the nineteenth century on the subject [insanity and the law]: *A Treatise on the Medical Jurisprudence of Insanity* (1838), and in the year before the trial the learned, though not very original, Prichard (who was to become a Commissioner for Lunacy in 1845), had published a similar work (Walker 1968, 89).

§ Tighe characterizes the notion of "moral insanity" as "the single most controversial concept in the emerging discipline of American forensic psychiatry" (Tighe 1983, 12).

> of exculpable insanity. He made extensive and almost exclusive reference to the work of the American physician, Isaac Ray, in his attempt to demonstrate that legally exculpable insanity should include more than disease of the intellect. (Quen 1968, 47)

In spite of Ray's influence on the *M'Naghten* decision, that influence was undone in great part by the House of Lords and its panel of judges, which "clarified" the *M'Naghten* decision so as to enshrine a knowledge test of mental competence in criminal procedure. Ray was attempting to have the law recognize the "wide range of mental disorders which primarily affected an individual's emotional and volitional capacities" which would affect imputations of responsibility (Tighe 1983, 30). However, the law was reluctant to make such an acknowledgment. Ray credited such resistance to jurists' ignorance, poor education, and lack of experience with the insane. To remedy this state of affairs, Ray worked to educate both the legal and medical communities to what he saw as the correct approach to psychiatric forensic problems. In 1866 Ray was put into contact with Judge Doe of the New Hampshire Supreme Court upon the latter's seeking medical opinion in a case before his court. Thus began a six-year correspondence between the two men that had a profound effect on the direction that medical jurisprudence was to take in the United States. This correspondence gives an intimate and detailed picture of the collaboration between Ray and Doe as they sought to have the question of insanity recognized as a question of science and not of law. "The resulting rule of law, established in *State v. Pike* and subsequently known as the 'New Hampshire rule,' has been proposed from time to time for wider adoption both in this country and in England" (Reik 1953, 183).

The New Hampshire Rule, or "product rule," states that a test of insanity ought to determine if the act in question was the "product" of a mental disease or defect, more closely reflecting Isaac Ray's desire to avoid cognitive tests of insanity such as the M'Naghten Rule. This "product rule" was adopted in the District of Columbia in 1954 and called the Durham Rule (*Durham v. United States*, 214 F.2d 862 [D.C. Cir. 1954]) but was later overturned in the case *U.S. v. Brawner*, 471 F.2d 969 (D.C. Cir. 1972), which replaced it with the rule enunciated in the American Law Institute's (ALI) Model Penal Code. Quoting from that model code, the following appears in the *Brawner* decision:

> A person is not responsible for criminal conduct if at the time of such conduct as a result of mental disease or defect he lacks substantial capacity either to appreciate the criminality [wrongfulness] of his conduct or to conform his conduct to the requirements of the law. *U.S. v. Brawner*, 471 F.2d 979 (D.C. Cir. 1972)

An "irresistible impulse" test first using the word *impulse* was employed in *Commonwealth v. Rogers*, 48 Mass 500 (Massachusetts 1844). The most influential early case to add this concept to *M'Naghten* was *Parsons v. State*, 2 80 854 (Alabama 1887), which referred to mental disease as causing a loss of power to choose between right and wrong, destroying free agency at the time of the alleged criminal act. A similar test was utilized in a federal court in *Davis v. United States,* 165 U.S. 373 (1897), which referred to the will or governing power of the mind being so destroyed that a defendant's actions are no longer subject to his will but are beyond his control. Although the New Hampshire Rule or "irresistible impulse test" currently is not relied on anywhere as the sole test, similar tests are often used in conjunction with the M'Naghten Rules or are incorporated in the volitional prong of the ALI insanity test. A form of the "irresistible impulse" test is the "policeman at the elbow" test.

Much controversy arose soon after physicians began testifying as psychiatric experts because their testimony often betrayed fundamental disagreements within the profession over the nature of mental disease. These disagreements seemed to suggest that either the expert was failing to make an objective evaluation (and many motives could be adduced for such failure, such as the personal or religious values of the expert, or the payment received from a party in the case) or the expertise itself was faulty. During the meetings of the AMSAII, references were made with greater regularity to the discomfort of its members over the contradictory testimony given by physicians and the attacks made during cross-examination on the credibility of expert witnesses as the nineteenth century advanced (Tighe 1983, 112).

Probably the most important battles fought in a courtroom in the late nineteenth century over these issues occurred during the trial of Charles Guiteau, the assassin of President Garfield. On July 2, 1881, Guiteau approached Garfield at Union Station in Washington, DC, and shot him as horrified Secretary of State James G. Blaine looked on. (Garfield did not die until September 19, 1881.) The motive for this slaying is not clear, but supposedly Guiteau had been disappointed in not having been appointed to a diplomatic post in France. Some of the most eminent men from the worlds of psychiatry and neurology appeared to testify at the trial (Rosenberg 1968).*

* Among these experts were Charles H. Nichols, superintendent of the Bloomingdale Asylum in New York; Charles Folsom of Harvard and the McLean Asylum in Boston; Edward C. Spitzka, neurologist; Fordyce Barker, professor of medicine and president of the New York Academy of Medicine; Allen McLane Hamilton, alienist; John Gray, superintendent of Utica Asylum in New York and editor of the *American Journal of Insanity*; William W. Godding, superintendent of the Government Hospital for the Insane in Washington, D.C.; James H. McBride, superintendent of the Asylum for Insane in Milwaukee, Wisconsin. This list is not exhaustive.

The conflicts that occurred during the trial, centering as they did on the concept of moral insanity, brought the tensions within psychiatry and between psychiatry and the emerging specialty of neurology into the open. John Gray, superintendent of Utica Asylum, vigorously opposed the idea of moral insanity. The neurologist Edward Spitzka defended it on the basis that brain disease could be selective in its manifestations. Gray, who had many years of experience treating the insane, did not believe it was possible for an individual to be insane in only part of his or her mind. Spitzka was rallying for reform of the insanity defense and wished to see the law recognize the recent advances that had been made in medical science. Much was made at the trial of the hereditary nature of insanity, a notion that had gained much favor toward the end of the nineteenth century.

All arguments proved futile. Garfield had been a popular president, and his assassin could not have gone unpunished. This case seems to fall within the pattern described earlier for eighteenth- and early nineteenth-century English cases. Those who succeed in their deadly aims are found guilty regardless of any pleas that might be made. Guiteau was indeed found guilty and was executed in 1882.

For forensic psychiatric practice, the Guiteau trial had two important results. The first is that by focusing the light of public attention on the insanity defense, much dissatisfaction was raised in the minds of the involved professionals and the public at large over the role that medical experts were playing in courtroom proceedings. (Almost exactly one hundred years later, in 1982, the trial of John Hinckley, who had made an unsuccessful attempt on the life of President Reagan, caused a similar reaction.) Second, the mandatory use of the hypothetical question* during the trial caused further frustration among the experts. These two results, coupled with the professional rivalries that were exacerbated by conflicting testimony, helped to precipitate various attempts at reform, which have occupied many in the legal and psychiatric professions in one form or another to this day.

As a response to the ongoing professional debate and attempts at reform, there emerged various medico-legal societies in the larger cities of the United States:

> The founding of the New York Medico-Legal Society in 1867 signalled the beginning of a new era in medico-legal relations. In this new era the still struggling sub-specialty of medical jurisprudence of insanity was transformed into a "science" as the physicians and attorneys interested in it became caught up in the general process of professionalization that was changing medical and legal practice at the end of the nineteenth century. (Tighe 1983, 182)

The New York Medico-Legal Society continues in an attenuated form to this day. The Society of Medical Jurisprudence in New York, which was incorporated on March 7, 1883, claims to be the oldest society of its type in the United States. The society continues to be composed of attorneys and physicians and provides a forum for outstanding individuals from various professions whose concern is the advancement of medical jurisprudence.

Not only do organizations seem to appear and disappear from the professional landscape, but energetic and forceful individuals who formed the backbone of the early forensic organizations came from a variety of professional backgrounds. For instance, Clark Bell, an attorney and founder and editor of the *Medico-Legal Journal*, described as "the first American journal devoted exclusively to medical jurisprudence" (Tighe 1983, 185), was either president or secretary of the New York Medico-Legal Society from approximately 1872 to 1918. Bell saw the major role of the society as an educational one, bringing together legal and medical people who could engage in "mutual education" as well as in educating the general public (Tighe 1983, 187). The society also engaged in vigorous attempts at reform of the system of expert testimony and the revision of notions of criminal responsibility.

In 1909,† after a National Conference on Criminal Law and Criminology was held at Northwestern University Law School, a committee was formed under the chairmanship of the law professor Edwin Keedy to reform the law of insanity. Keedy enlisted eminent attorneys, judges, and psychiatrists to serve on this committee, which was to focus on tests of responsibility, the forms in which verdicts were cast, and expert testimony. Lack of agreement among the disparate professional elements involved meant that little was accomplished in the way of reform (Tighe 1983, 314).

As the chairman of the committee, Keedy exemplified the position of the legal profession. "According to Keedy the medical expert's only task was to give the jury technical

* It had been the practice in American courts of law for attorneys to be required to pose questions to expert witnesses only as hypothetical questions. Legal tradition construed an expert opinion on the actual facts of any particular case as an invasion of the province of the jury whose most important function was to decide such questions of fact. This practice led to the creative phrasing of questions beginning with the word "suppose" and recreating in almost every detail the case being tried except for the actual names, dates, and other identifying information. (See Kidd 1915, for an attempt in one American jurisdiction to correct this practice as part of larger evidence reforms.)

† In this same year (1909), William Healy, a British-born psychiatrist who had graduated from the University of Chicago Medical School, became the director of the Psychopathic Institute of the Cook County (Chicago) Juvenile Court, which had been opened in 1899 as the first court of its kind. The Psychopathic Institute was also the earliest such court clinic in the United States. Some of the most prominent forensic psychiatrists, such as Jonas Rappeport in Baltimore and Richard Rosner in New York, worked in such court-related psychiatric institutions.

assistance in evaluating a defendant's mental state" (Tighe 1983, 361). This model of psychiatric expert testimony contrasted sharply with the one that was supported by the psychiatrists, especially Adolph Meyer and William A. White. These psychiatrists wished to have the concepts of medical and legal insanity integrated, and the jury determination of insanity replaced by psychiatric determinations. Such a model of the expert's role in the courtroom contradicted basic rules of evidence and legal procedure. Trial by jury is a right protected by the Constitution of the United States. All witnesses may be cross-examined and all facts in question must be put to the jury for determination.

Further, psychiatrists such as William A. White (and later Karl Menninger) attacked the principles upon which criminal law and criminal procedure were predicated. They argued that punishment for crime often prevented the rehabilitation it sought to achieve, that such punishment merely expressed the need for revenge, and that legal decision making in such matters ought to be surrendered entirely to scientists. The arguments of psychoanalysts such as White and Menninger gained influence as psychoanalysis gained prestige.

Psychiatrist Bernard Diamond was instrumental in the development of the diminished capacity defense in California. Diminished capacity permitted gradations of punishment by finding gradations of guilt. It allowed the psychiatrist to explain why a defendant committed a crime often using psychodynamic terminology. In California, two separate trials are held: one to establish guilt or innocence and another afterward to determine sanity or insanity (Diamond 1961, 74). Until *People v. Wells*, 33 Cal.2d 330 (1949), psychiatrists were excluded from testifying until the second stage of the bifurcated trial. *People v. Wells* established that mental illness could negate the *mens rea* (criminal intent) required to convict for a crime and evidence supporting such negation could be introduced at the primary trial.

Diamond testified in another, later case, *People v. Gorshen*, 51 Cal.2d 716 (1959), which permitted testimony and opinions regarding specific intent in the absence of legal insanity:

> The essence of my [Diamond's] testimony was that Gorshen killed, not because he was insane, but rather as a defense against insanity. Although he knew right from wrong in the sense of *M'Naghten*, although he appeared to have premeditated, deliberated, and to have had the requisite criminal intent of malice, that he was, nevertheless, not a free agent. That he was suffering from an uncontrollable compulsion, the consequence of mental disease. (Diamond 1961, 79)

The California Supreme Court on appeal accepted the argument made by Diamond and other psychiatrists filing *amici curiae* briefs in the *Gorshen* case. It allowed that a showing of "mental abnormality not amounting to legal insanity" could provide evidence that the defendant did not possess the specific mental state required for conviction of a crime but still could be found guilty of a lesser-included crime. However, in response to the furor over the trial of Dan White, the assassin of San Francisco Mayor George Moscone and Supervisor Harvey Milk, the California legislature has undermined most of Diamond's efforts by eliminating diminished capacity as a defense. Nevertheless, the diminished capacity defense has been utilized in some other states. A *mens rea* defense of diminished actuality was retained in California (Weinstock et al. 1996).

During his long and distinguished career, Diamond also supported an approach to forensic psychiatry in which the psychiatrist in criminal trials would become an advocate, testifying with total honesty solely for the defense. (See Diamond [1985] for a characterization of this approach, which Diamond contrasts with the approach of the late Seymour Pollack, a forensic psychiatrist who established one of the earliest U.S. forensic training programs at the University of Southern California.)

In terms of forensic psychiatry, the status of psychiatrist as expert had already been achieved prior to the Freudian "revolution." Nevertheless, the movement away from interpreting insanity solely as a chemico-physiological imbalance or a hereditary degeneration, to the view that dysfunctional mental states and attendant behavioral manifestations arose from environmental and familial influences, opened every aspect of social and psychological life to the scrutiny of the psychiatrist. Psychiatric expertise began to be sought in an ever-widening range of situations. Such an increase in the perimeter of the psychiatrist's jurisdiction and responsibility is a continuing theme within medical jurisprudence; however, recent developments have moved psychiatry back toward the biological.

Forensic psychiatry failed to professionalize during its early history not merely because the pioneers and reformers were overzealous or scattered in their energies, which, in fact, they were. On the one hand, figures such as Isaac Ray (a physician), Clark Bell (attorney), and Edwin Keedy (attorney) were striving to organize across professional lines—that is, by including physicians from a variety of specialties and attorneys in their struggles. On the other hand, the task of such reformers was made doubly difficult since they were attempting to achieve meaningful substantive reform in the area of their specialization without having first formally specialized and/or professionalized it. Thus, the boundaries of the specialty were unclear and the centers of power were diffuse.

Although the formation of the medicolegal societies of the nineteenth and early twentieth centuries provides evidence that movement toward formal organization had begun, the major player in this respect continued to be AMSAII. Through its journal, the *American Journal of Insanity* founded in 1844, AMSAII played an important role in educating the growing psychiatric community to the importance of understanding legal issues.

At its annual meeting in Washington, DC, in 1892, AMSAII changed its name to the American Medico-Psychological Association (AMPA) and adopted a new constitution. This change recognized the changed shape of the psychiatric profession inasmuch as the medical superintendent no longer dominated professional affairs. Standing committees did the major work of AMSAII and AMPA. In 1882 a committee on the "criminal responsibility of the insane" was added (Barton 1987, 88–89). Neither AMSAII, nor its successor, AMPA, was distinguished by vigorous activity on the national scene. It did not provide dynamic leadership for the growth of a subspecialty in forensic psychiatry, let alone the psychiatric profession generally, until after World War I.

In 1921, the AMPA again changed its name to the American Psychiatric Association (APA) and by that time had 1000 members (Barton 1987). Adolf Meyer, a leader in the specialty before and after the First World War, assisted in promoting research in psychiatry and spurred changes in medical education to include greater attention to psychiatry. The emergence of forensic psychiatry could not have occurred without the widening exposure of physicians to education in psychiatry both in their undergraduate and graduate medical education. The addition of psychiatry to the medical school curriculum was slow in coming. Even by the late 1930s, psychiatry had not been added as a mandatory part of the curriculum at institutions such as the medical school of the University of California, San Francisco, which had only one psychiatrist on its faculty at the time. Forensic psychiatry was also absent from medical school curricula.

Except for the medico-legal societies described above, forensic psychiatry was not represented by any formal organization; however, there was movement in the APA with respect to the recognition of the growing importance of forensic issues:

> In 1925 the first report of the new Committee on Legal Aspects of Psychiatry of the American Psychiatric Association was published. Dr. Karl Menninger submitted the reports as chairman. It marked a true turning point in the history of the problem [the interface of law and psychiatry], and Karl Menninger's name must rightly occupy an honorable place among the pioneers of an important and difficult task. (Zilboorg 1944, 579)

This committee had contacts with the Section on Criminal Law and Criminology of the American Bar Association.

In 1934, a section of forensic psychiatry was initiated by the APA under the chairmanship of William Alanson White, who had been president of the APA (1924–1925) and was one of the most vocal critics from the psychiatric community of the criminal justice system. By the end of World War II, the general unresponsiveness of the APA to the growing problems surrounding the practice of psychiatry became patent and had been observed by William Menninger. He and a group called the "young turks" went on to form the Group for the Advancement of Psychiatry (GAP) in 1946 to restructure the APA because of their perception that the APA had been less than responsive in supporting the military during World War II. In fact, major changes in the APA structure were effected through the urging of GAP members, including the establishment of an office of medical director (Barton 1987, 118).

The Council on Psychiatry and Law (CPL) of the APA emerged during 1979–1980 out of the Council on Governmental Policy and Law when Alan Stone was APA president. The CPL has been very active in formulating policy proposals for its parent body. Participating with other groups, the CPL breaks up into smaller groups as needs warrant; for instance, the Insanity Defense Work Group developed an APA statement on the insanity defense in December 1982. The APA recommended elimination of the volitional prong of the insanity defense, but use of the word "appreciate" instead of the more cognitive word "know" appeared to minimize the effect of the change. It was prompted by the public furor that arose over the insanity verdict in the case of John Hinckley, who had attempted to assassinate President Reagan. The American Medical Association (AMA) had recommended abolition of the insanity defense and its replacement by a *mens rea* defense, and the APA statement was seen by many as a political move to stem antipsychiatric public sentiment. H. Keith Brodie, MD, president of the APA, who signed the foreword to the APA statement, characterized it as follows: "This is the first comprehensive position statement on the insanity defense to be developed and adopted by APA" (APA 1984, 4). Considering the age of the APA and its antecedent organizations, this characterization reveals much about activity within the APA and the caution it has shown in taking formal positions on forensic issues.*

However, it is not from any reforms within the APA itself or action on the part of any of its committees that the formal organization of forensic psychiatry has arisen. Rather, this subspecialty came into existence through the efforts of psychiatrists particularly interested in forensics who maintained professional relationships with law schools and forensic organizations. Through the 1950s, 1960s, and 1970s, law schools became interested in having psychiatrists on their faculties. Psychiatrists such as Bernard Diamond at the University of California, Berkeley; Jay Katz at Yale Law School; Alan Stone at Harvard Law School; and Andrew

* Since 1952, the APA has given the Isaac Ray Award to an individual who has made an outstanding contribution to "forensic psychiatry or to the psychiatric aspects of jurisprudence." Since 1967, the APA joined by the American Academy of Psychiatry and Law in 1982 as cosponsor) has given the Manfred Guttmacher Award for outstanding contributions to the literature of forensic psychiatry.

Watson at the University of Michigan Law School are all examples of this trend. Ultimately, training programs in forensic psychiatry arose. One of the earliest and most notable was the program developed by Seymour Pollack at the University of Southern California. The Western Psychiatric Institute in Pittsburgh is another important center of forensic psychiatric training and activity.*

Probably the most important organization to give attention to the relations of psychiatry and law has been the American Academy of Psychiatry and Law (AAPL). Jonas Robitscher, lawyer and psychiatrist, characterizes the formal inception of AAPL in 1969 in the following fashion:

> This formal group [AAPL] was the outgrowth of an informal group of about 15, mainly directors of forensic psychiatry fellowship training programs, who had met in connection with the American Psychiatric Association meeting in Boston in 1968. This new group now [1972] has about 250 members, all interested in some phase of legal psychiatry.... The by-laws of AAPL list six aims: to exchange ideas and experience among forensic psychiatrists in North America; to elevate the standards of study and practice in this field; to develop training programs for psychiatrists desirous of acquiring skills in forensic psychiatry; to take leadership in initiating and monitoring research in the field; to improve relationships between psychiatrists on the one hand and attorneys, legislators, jurists, and penologists on the other; and to take leadership in informing the public of the needs of those involved with the law and the contributions available from psychiatry. (Robitscher 1972, 316 [921])

AAPL is a thriving and vibrant professional organization that publishes a newsletter (in January, April, and September) and quarterly journal *(Journal of the American Academy of Psychiatry and the Law*), and sponsors an annual meeting. Under the direction of Jonas Rappeport as founding medical director, AAPL became the largest forensic psychiatric organization in the United States. There are chapters of AAPL throughout the United States with the first chapter organized by Richard Rosner in the New York area, known as the Tri-State Chapter. AAPL maintains an active liaison with the American Academy of Forensic Sciences (AAFS). AAPL adopted ethical guidelines in 1987, which have undergone revision. The last revision was in 2005.

The AAFS founded in 1948 (as the American Medicolegal Congress) is composed of experts from diverse disciplines including, but not limited to, psychiatry, pathology, toxicology, anthropology, engineering, and ballistics. Individuals active within the AAFS have made major contributions to the furtherance of the professionalization and specialization of forensic psychiatry. Chief among such contributors was Maier Tuchler, a psychiatrist with extensive experience in forensics, who worked assiduously to form a certifying body for forensic psychiatry.† Apparently an idea for such a certifying body had first been proposed by Lowell Sterling in the early 1950s when he was chairman of the psychiatry section of AAFS. Such a proposal was also made in the mid-1950s by Ralph Banay, a psychiatrist active in the world of criminalistics, and editor of the *Journal of Correctional Medicine and Social Therapy*. However, an earlier movement forming specialty boards had occurred in the 1930s‡ and resistance had arisen later within the medical community to what was seen as overspecialization.

When AAPL was approached to cosponsor a forensic board with the AAFS, some of the original founders of AAPL looked upon attempts at certification with skepticism. These attempts created dissension in what otherwise was a "healthy organization" and generated the fear that certification might ultimately lead away from the educational mission of AAPL, and create elites within the organization. These objections ultimately subsided when it was realized that AAPL would not be the certifying body itself but rather only a sponsoring agency.

The way ultimately opened for the formal organization of a board in June 1976, with the participation of the AAFS, AAPL, liaison with the APA and the AMA, and financing from the Legal Enforcement Assistance Administration (LEAA). The first members of the American Board of Forensic Psychiatry§ (ABFP) were all highly experienced in forensic psychiatry, were involved in teaching, and had been certified by the American Board of Psychiatry and Neurology (ABPN).

* For an excellent (although somewhat dated) discussion of the changes taking place within forensic psychiatry see Robitscher (1972).

† I am indebted to and would like to express my appreciation of the late psychiatrist Stanley Prentice, for allowing me access to materials he prepared in advance of writing a history of the American Board of Forensic Psychiatry. Those materials were invaluable in creating my own encapsulated history of the American Board of Forensic Psychiatry.

‡ The ABA [American Board of Anesthesiology] was one of nine boards established between the years 1933 and 1938, a period which saw the flowering of the specialty board movement in the United States, the others being the American Board of Pediatrics (1933), of Orthopedic Surgery (1935), of Psychiatry and Neurology (1935), of Radiology (1935), of Urology (1935), of Internal Medicine (1936), of Pathology (1936), and of Surgery (1937) (Little 1981, 317).

§ The first board of directors of the American Board of Forensic Psychiatry were: Walter Bromberg, MD; Bernard Diamond, MD; Zigmond Lebensohn, MD; Herbert Modlin, MD; Joseph Paterson, D.Crim., Irwin Peff, MD; Seymour Pollack, MD; Stanley Portnow, MD; Jonas Rappeport, MD; Robert Sadoff, MD; John Torrens, MD; and Maier Tuchler, MD.

It had been decided by the founders of the ABFP that no members would be "grandfathered" into certification—that is, even those psychiatrists who organized the ABFP would have to sit for the certifying examination. The board required that psychiatrists (limited to those practicing in the United States and Canada) wishing to be certified in forensic psychiatry also be certified by ABPN. In addition, five years of post-residency experience was required, with substantial involvement in forensic work. (Consideration was given for time spent in forensic fellowship training programs. One year of credit was given for a law degree.) Two examinations had to be successfully passed: one written, given during the annual meeting of the APA, and one oral, given during the annual meeting of the AAPL. Candidates needed to pass the written examination before taking the oral. Mechanisms were in place for retaking examinations that were not passed and for appealing board decisions. Richard Rosner was instrumental in the creation of standards for accrediting fellowship programs in forensic psychiatry as well as the development of the Accreditation Council on Fellowships in Forensic Psychiatry (ACFFP). Its processes were implemented in 1988, and the first programs were accredited in 1989. The Accreditation Council was supported financially by AAFS and was given administrative support by AAPL. Both organizations became cosponsors.

Neither the mechanisms established by the American Board of Forensic Psychiatry for certifying forensic psychiatrists nor the accreditation procedures of the Accreditation Council on Fellowships in Forensic Psychiatry are now used. After some years of struggle and negotiation, a decision was made by the American Board of Medical Specialties to recognize forensic psychiatry as a full-fledged psychiatric subspecialty. Qualifying examinations are no longer conducted under the auspices of the ABFP but are administered by the American Board of Psychiatry and Neurology. Such formal recognition has had an impact not only on the credential that forensic psychiatrists come to obtain but also on the nature of their postgraduate education.

In 1996, the Accreditation Council for Graduate Medical Education (ACGME) developed standards for certification in forensic psychiatry relying heavily on those developed by the ACFFPF. The ACGME began accrediting programs in 1997 and as of 2015 there are 40 such programs throughout the United States. When the ABPN began certifying forensic psychiatrists by examination, there were no approved ACGME fellowship programs. Thus, the requirements for taking the first examination could have been fulfilled by attending any one of a number of "nonapproved" post-residency programs or through a number of years practicing extensively in the field. In 1999, the "practice track" was eliminated. Since 2001, only completion of a fellowship program in forensic psychiatry at an ACGME-approved program is accepted as fulfilling the requirements for examination. Recertification examinations began in 2003 for those previously certified in forensic psychiatry. Of course, board certification in psychiatry is required before attempting qualification in the subspecialty of forensic psychiatry. From 1994 through 1999, 1310 board certified psychiatrists were qualified in forensic psychiatry by the American Board of Psychiatry and Neurology. At this point, the ABPN has routinized the process of awarding certification in forensic psychiatry and regular examinations are given to applicants who complete ACGME certified fellowship programs. Since 2014, following the initial certification and any recertification in forensic psychiatry, continuous maintenance of certification is required to retain the certification. This process like in other medical specialties requires more than just an examination.

After traveling a circuitous and difficult path, forensic psychiatry has emerged out of a history extending back to the beginning of civilization in the West. This emergence has not been smooth; there have been many breaks and bumps in the trail. It is only within the last 250 years that physicians or psychiatrists have been asked into courts to act as expert witnesses. Although there have been many attempts made to reorganize or reform the nature of the social action performed by forensic psychiatrists, those attempts have only had limited success. For instance, there is much dissatisfaction with the M'Naghten Rules, but many states retain them despite much psychiatric opposition. Some jurisdictions in recent years have even returned to *M'Naghten* from the ALI test in response to unpopular trial verdicts and public clamor. Although new challenges will undoubtedly confront forensic psychiatry, the next chapter of this history will be written by a subspecialty that has gained formal recognition and which is well positioned to meet those challenges.

Appendix 3.1 Important dates in the history of forensic psychiatry

(Dates BC are approximate)	
3000 BC	Imhotep combines the role of priest/physician/statesman and scientist.
1850 BC	First murder trial in Babylonia in which an expert witness (midwife) appears.
1800 BC	Code of Hammurabi makes early recognition of importance of intent in criminal law but punishes most crimes with death.
1200 BC	Hebrew law establishes the intent of actor when establishing guilt for murder.
460 BC	Birth of Hippocrates (died 377 BC).

(*Continued*)

Appendix 3.1 (*Continued*) Important dates in the history of forensic psychiatry

	(Dates BC are approximate)
450 BC	Twelve Tables of Roman Law refers to the legal incapacities of children and the insane; provided for guardianship of fools by family or paternal relatives.
	Lex Aquila in Roman law does not hold a man accountable for damage to property when caused without negligence or malice.
	Lex Cornelia punishes those who injured the personality of victim or lowered esteem in which victim was held but exempted children and the insane when they committed such injury.
AD 130	Birth of Galen (died AD 201).
AD 528	Code of Justinian likens the insane person to someone who was absent, asleep, or dead, although the insane did keep their property and their offices. When considering crime, the insane were excused as were children who could not form the requisite intent.
AD 1256	Henry de Bracton writes *On the Laws and Customs of England,* a discussion of the "wild beast test."
AD 1272	Enactment of *Praerogativa Regis* or King's Right in the reign of Edward 1. Established system whereby the king conserved the property of an individual who became insane after birth; however, the property of congenital fools reverted entirely upon the king. Special commissions were held to determine mental status and property rights.
AD 1292	City of Bologna establishes the first expert medical investigatory service in Europe.
AD 1302	One of the first recorded medico-legal autopsies performed in Bologna.
AD 1487	First possible publication date of the *Malleus Maleficarum,* or *Witches Hammer,* written by two Dominican friars as a handbook for witch-hunters.
AD 1648	Wardships such as those established by the *Praerogativa Regis* are transferred to the English Court of Chancery (where they are still heard today).
AD 1664	Sir Thomas Browne testifies in the trial of two women for witchcraft.
AD 1681	Thomas Willis publishes his *Opera Omnia,* which describes various cerebral diseases and a host of psychiatric disorders.
AD 1724	Arnold case.
AD 1736	Publication of Matthew Hale's *History of the Pleas of the Crown.*
AD 1752	Pennsylvania Hospital opens in Philadelphia with one of its expressed intents ministering to those with mental diseases; first hospital of its kind in colonial America.
AD 1760	Trial of Earl Ferrers; first criminal trial in which physician appears as expert witness in English law on issue of mental state.
AD 1800	Hadfield case.
AD 1810	Benjamin Rush delivers a lecture entitled "Lecture on the Medical Jurisprudence of the Mind."
AD 1812	Bellingham case.
	Benjamin Rush writes *Medical Inquiries and Observations on the Diseases of the Mind.*
AD 1838	Isaac Ray writes *A Treatise on the Medical Jurisprudence of Insanity.*
AD 1840	*Oxford* case.
AD 1843	*M'Naghten* case.
AD 1844	First issue of the *American Journal of Insanity.* Founding of the Association of Medical Superintendents of American Institutions for the Insane.
	Commonwealth v. Rogers: first use of irresistible impulse.
AD 1847	Founding of the American Medical Association.
AD 1849	First American treatise on neurology, *An Inquiry Concerning the Diseases and Functions of the Brain and Spinal Cord,* written by Amariah Brigham.
AD 1867	Founding of the New York Medico-Legal Society.
AD 1872	John Ordronaux is appointed first commissioner of lunacy in New York State.
AD 1877	Founding of Massachusetts Medico-Legal Society.
AD 1881	Trial of Charles Guiteau for assassination of President Garfield.
AD 1883	Founding of the Society of Medical Jurisprudence of New York City.
AD 1884	Founding of the Philadelphia Society of Medical Jurisprudence.
AD 1885	Founding of the Rhode Island Medico-Legal Society.
AD 1886	Founding of the Chicago Medico-Legal Society.

(*Continued*)

Appendix 3.1 (*Continued*) Important dates in the history of forensic psychiatry

	(Dates BC are approximate)
AD 1887	*Parsons v. State.*
AD 1890	Founding of the Denver Medico-Legal Society.
AD 1892	AMSAII changes its name to American Medico-Psychological Association.
AD 1897	*Davis v. United States.*
AD 1900	Publication of Sigmund Freud's *Interpretation of Dreams.*
AD 1909	National Conference on Criminal Law and Criminology held at Northwestern University Law School; attorney Edward Keedy forms committee to reform insanity law. First psychiatric court clinic established in Chicago at Juvenile Court by William Healy.
AD 1921	American Medico-Psychological Association changes its name to American Psychiatric Association; the *American Journal of Insanity* changes its name to the *American Journal of Psychiatry.*
AD 1925	Karl Menninger as its chairperson submits the first report of the Committee on Legal Aspects of Psychiatry of the American Psychiatric Association.
AD 1933	Founding of American Board of Medical Specialties (at first named Advisory Board for Medical Specialties).
AD 1934	William Alanson White chairs the first section on forensic psychiatry initiated by APA.
AD 1935	Founding of American Board of Psychiatry and Neurology.
AD 1946	William Menninger founds Group for the Advancement of Psychiatry.
AD 1948	Founding of American Academy of Forensic Sciences (as American Medico-legal Congress).
AD 1949	*People v. Wells.*
AD 1952	First Isaac Ray Award presented by the American Psychiatric Association to Winfred Overholser, superintendent of St Elizabeth's Hospital; award is made to an individual who has made outstanding contributions to the field of forensic psychiatry.
AD 1954	*Durham* case: crime a "product" of mental disease or defect (Durham acquitted).
AD 1959	*People v. Gorshen.*
AD 1967	Manfred S. Guttmacher Award established by American Psychiatric Association to honor outstanding contributions to forensic psychiatry; first presented in 1972.
AD 1969	Founding of American Academy of Psychiatry and the Law.
AD 1972	*Brawner* case: Durham Rule abandoned; ALI rule adopted.
AD 1976	Founding of American Board of Forensic Psychiatry.
AD 1982	*Barefoot v. Estelle* (1982) 463 U.S. 880: Supreme Court of the United States found that psychiatrists are competent to testify to the question of future dangerousness of an individual convicted of capital crime and sentenced to die; American Psychiatric Association joined defense as *amicus curiae* in opposing this outcome.
AD 1987	AAPL adopts ethical guidelines.
AD 1988	Accreditation Council on Fellowships in Forensic Psychiatry implements its processes.
AD 1989	First programs accredited by Accreditation Council on Fellowships in Forensic Psychiatry.
AD 1992	The American Board of Psychiatry and Neurology first recognizes forensic psychiatry as an area of subspecialization.
AD 1993	American Board of Psychiatry and Neurology and American Board of Medical Specialties are preparing to formally establish forensic psychiatry as a subspecialty and administer appropriate examinations.
AD 1994	American Board of Psychiatry and Neurology gives its first examinations for added qualifications in forensic psychiatry.
AD 1996	The ACGME establishes standards for accreditation for training in forensic psychiatry.
AD 1997	The ACGME accredits its first fellowships in forensic psychiatry. The name for certification in forensic psychiatry was changed by the American Board of Psychiatry and Neurology to certification in the subspecialty of forensic psychiatry.
AD 1999	Last certification examination of forensic psychiatrists who did not graduate from any forensic psychiatry fellowship program.
AD 2001	Last certification examination of forensic psychiatrists who graduated from a non-ACGME approved program in forensic psychiatry.
AD 2003	First recertification examination for those previously certified in forensic psychiatry by the American Board of Psychiatry and Neurology.

Forensic psychiatric report writing

MICHAEL A. NORKO AND ALEC BUCHANAN

INTRODUCTION

The written report occupies a focal point in contemporary forensic mental health practice, demonstrating in tangible form the skills and efforts of the expert and providing the most common form of communication of evaluation results to the legal system (Griffith et al. 2010; Norko and Buchanan 2011; Buchanan and Norko 2013). Report writing is important because at stake are the significant interests of the litigants (Wills 2011) as well as the reputation of the evaluator.

The written report appeared in American jurisprudence in the mid-nineteenth century, during a time in which adversarial expert psychiatric testimony was becoming both more commonplace and more suspect (Weiss et al. 2011). Isaac Ray argued in 1873 that the use of written expert opinions allowed the expert to better convey the reasons for his opinions in a logical and coherent manner (Weiss et al. 2011), which remains one of the major objectives of the written report. Attempts in the early twentieth century to legally regulate expert reports were far less successful than the work of professional organizations in improving the quality of reports. The latter includes the efforts of the American Board of Forensic Psychiatry (ABFP) and the American Academy of Psychiatry and the Law (AAPL) to establish guidelines about report preparation, content, and structure (Weiss et al. 2011).

Scholarly contributions over the past 40 years have articulated multiple purposes for the written forensic report: to effectively communicate information, including narrative forms, to legal audiences; to prepare for trial or deposition testimony; to facilitate mental health treatment for an evaluee; to document that the evaluation was conducted properly; and to provide a mechanism for the evaluation and improvement of clinical and forensic practice (Weiss et al. 2011).

Context—Professionalism

Because forensic reports are prepared by mental health professionals, the work of conducting evaluations and documenting them is appropriately contextualized within the realm of professionalism. A proper forensic report is not simply a documented mental health evaluation (Griffith and Baranoski 2007). It requires an appreciation of the complicated interplay of multiple, and often competing, forces in medicine, law, and society (Norko and Buchanan 2011). Three overlapping domains of professionalism are considered here: confidentiality, ethics, and humanism.

CONFIDENTIALITY

The notice given to an evaluee about the limits of confidentiality in a forensic evaluation are based on the distinctions between the professional roles of treater and forensic evaluator, which are most often seen as conflicting roles in contemporary practice (Appelbaum 1997; Strasburger et al. 1997). It is presumed that individuals will ordinarily tend to view members of helping professions as therapeutic agents, when in fact the work of the forensic expert may or may not be helpful to an evaluee. Therefore, forensic evaluators give notice to evaluees at the start of an evaluation about how the therapeutic relationship, with its expected confidentiality, is not applicable to the evaluation at hand (AAPL 2005). Documentation of this notice and the evaluee's comprehension is an expected component of written forensic reports in the United States (see, for example, the report structure adopted by the ABFP in Silva et al. 2003, 34). Although such notice and its documentation can become routinized, the mental health professional must remain cognizant of many subtleties and complexities about confidentiality in forensic practice, including the technicalities and continued vagaries of the Health Insurance Portability and Accountability Act (HIPAA) requirements as they relate to forensic practice (Zonana 2011).

ETHICS

Honesty and striving for objectivity are pillars of the AAPL Ethics Guidelines (AAPL 2005). Scholars have expressed a range of ideas about truth-telling in forensic practice: psychiatrists have no truth to offer in court (Stone 1984); truth-telling has objective and subjective components (Appelbaum

1997); truth-telling requires cultural considerations (Griffith 1998); truth-telling is conveyed through narrative authenticity (Candilis et al. 2001; Griffith 2005); and truth in forensic settings requires a postmodern understanding of subjectivities and various cultural contexts (Martinez and Candilis 2011). Some discussions of forensic ethics have distinguished forensic and clinical practice (Appelbaum 1997; Strasburger et al. 1997), and others have placed forensic ethics within the broader historical perspectives of medical ethics (see Chapter 8; O'Grady 2011; Weinstock 2013) or attempted to reconcile these approaches via the concept of robust professionalism (Martinez and Candilis 2005, 2011). Within this latter approach, Martinez and Candilis have identified four ethics principles to guide forensic report writing: respect for persons; respect for privacy and confidentiality; respect for consent processes; and commitment to honesty and striving for objectivity (Martinez and Candilis 2011, 64–65).

HUMANISM

Resnick and Soliman have described humanity as one of the four principles of good report writing (Resnick and Soliman 2011, 2012). It is important to grasp that forensic reports are not detached, technical descriptions; they are stories about people requiring narrative constructs (Griffith and Baranoski 2007). The challenge is to do justice to the several, and sometimes competing, narrative voices that are part of the circumstances under investigation in a forensic report (Griffith et al. 2011; Buchanan and Norko 2011b, 2013).

Griffith et al. have articulated several reasons for including all relevant expository narratives in a report: doing so allows each person to be heard in the report and demonstrates that the expert considered fully the significant accounts available; it demonstrates respect for persons; and it avoids accusations that reports contradictory to the expert's conclusions were excluded, distinguishing "the ethical expert from the hired gun" (Griffith et al. 2011, 71). Buchanan and Norko have noted the challenges faced by the report writer in navigating and arbitrating the potential tensions and frank inconsistencies among multiple narratives while producing a report that is more clarifying than confounding (Buchanan and Norko 2013).

Respect for persons is a recurring and prominent theme in discussions of the ethics of forensic practice. It is tied to concerns for privacy and confidentiality, informed consent, and narrative authenticity. Respect for persons may sometimes, though, compete with the strict requirements of confidentiality. This occurs, for example, when deciding whether to seek the evaluee's consent to obtain important collateral information from individuals known to the evaluee who do not possess confidential or protected information about the evaluee (Buchanan and Norko 2013). There is no generally agreed solution to this dilemma, requiring report writers to make their own determinations. It may be helpful for the report writer to consider the ideals of compassion (Candilis et al. 2001; Griffith 2005; Norko 2005) and dignity (Buchanan 2014, 2015) in assessing the appropriateness of alternate approaches to the evaluee. The former is "an approach to justice that allows us to attend to and engage the humanity of all the subjects of our evaluations" (Norko 2005, 388), including the multiple aspects of their suffering (Candilis et al. 2001). The latter extends our concern and respect for persons deeper than the boundaries of consent, confidentiality, and autonomy through an established principle of medicine and human rights (Buchanan 2014, 2015).

A related consideration is the demonstration of empathy toward the evaluee. Appelbaum sees an appropriate use of "forensic empathy" in efforts to achieve "awareness of the perspectives and experiences of interviewees" (Appelbaum 2010, 44). Evaluators are cautioned against the use of "reflective empathy" that expresses therapeutic concern for the evaluee, which militates against the notice of the limits of confidentiality given to the evaluee (Shuman 1993, 298; Brodsky and Wilson 2013). Brodsky and Wilson have argued, however, that modest expressions of empathy convey humanity, respect for the person, and a recognition of the evaluee's emotional reality without precluding objectivity (Brodsky and Wilson 2013).

PREPARATION FOR REPORT WRITING

The forensic expert should adopt a consistent and purposeful approach to preparation for writing a report (Wills 2011). In their initial contact with the retaining party, experts must determine whether they possess the requisite knowledge, skills, training, and experience to answer the forensic question at hand (AAPL 2005). The expert must have sufficient time to conduct the evaluation thoroughly, and must be able to meet any jurisdictional requirements for expert testimony (Wills 2011). The expert also needs to consider any potential barriers to ethics concerns such as objectivity, honesty, and respect for persons (Wills 2011; Resnick and Soliman 2012). Wills recommends the use of checklists for these initial determinations (Wills 2011).

Actual report preparation begins with gathering and cataloging the available data and identifying missing data that should be requested or identified in the report as missing if unavailable (Resnick and Soliman 2012). The choice of format for the report will depend on the purpose of the report and its intended audience (Reid 2011). The preparation of an outline sufficiently detailed for the case is a useful next step, with headings and subheadings that are appropriate to the legal questions posed (Resnick and Soliman 2012). The outline of the opinion section is particularly important and should allow the writer to determine the strength of data supporting the opinion and the relative importance of these data elements, data that do not support the conclusion, and whether they suggest revisions to the opinion or concessions to be conveyed and explained (Wills 2008, 2011; Resnick and Soliman 2012). This prioritizing prepares the expert to present the strongest evidence supporting the opinion first, and to reformulate or omit the weakest evidence (Wills 2011; Resnick and Soliman 2012).

REPORT CONTENT

Structure

There is a reasonable consensus in the literature about the important elements to be included in forensic reports, as well as their general order (Griffith et al. 2010), although no single format is required for all forensic reports (Wettstein 2010b). Depending on the level of detail ascribed to each section, report structure can be outlined in as little as three sections (introduction, data, and conclusions) or as many as 11 sections, as was done by the American Board of Forensic Psychiatry in the 1980s (see Silva et al. 2003).

Although the precise structure and headings of the report will vary with the purpose of the report (Reid 2011; Resnick and Soliman 2011), a general outline for the report can be described as follows (Silva et al. 2003; Buchanan and Norko 2011a).

Introductory material includes identification of the agent requesting the evaluation and the person evaluated; the purpose of the evaluation, including the questions to be addressed; the circumstances of the request; sources of information used in the report, including dates and duration of all interviews conducted; the notice of confidentiality given to the evaluee; and a list of any documents appended to the report.

The data section or body of the report includes relevant background information (e.g., social and developmental history, educational and employment history, relationship and sexual history, past psychiatric and medical history, family history, legal history); description of the events in question from the available sources, including the evaluee; mental status examination findings; and findings from psychological and other testing.

The conclusion section contains the evaluator's opinion about the referral questions and the reasoning supporting the conclusions reached. Depending on the type of the report, it may or may not include a formal diagnostic assessment.

Draftsmanship

Resnick and Soliman note four principles for good report writing: clarity, simplicity, brevity, and humanity (Resnick and Soliman 2011, 2012). The last of these has been described above. Clarity consists in "good formatting adequate information, appropriate word choices, good grammar, and clear attribution" (Resnick and Soliman 2012, 415). Their recommendations are outlined in Table 4.1. Attention to these principles is useful in achieving Ackerman's guidance to write "in a manner that increases the likelihood that [the report] will be read in its entirety" (Ackerman 2006, 60).

Common types of reports

CRIMINAL

There are several types of criminal forensic reports, each with its own particular question(s) to be addressed, which informs the structure and content of the report. It is important that the evaluator clearly understand what is required, as the research literature demonstrates that criminal reports commonly address the wrong or extraneous matters (Ciccone and Jones 2011). AAPL Guidelines provide a rich resource for the evaluation of competence to stand trial (Mossman et al. 2007, with guidance regarding the written report on pages S48–S51) and criminal responsibility (AAPL 2014, where the report is discussed on pages S26–S28).

Criminal reports include the following categories:

- Competency—to stand trial, to confess, to represent oneself in court, to be executed
- Criminal responsibility—not guilty by reason of insanity, extreme emotional disturbance, *mens rea*

Table 4.1 Principles of report writing

Clarity	Format report pages for ease of readability
	Make report self-sufficient (provide or summarize all necessary information)
	Identify sources of all information
	Avoid ambiguity
	Use correct verb tense and appropriate word choices
	Clarify inconsistent data
Simplicity	Avoid unnecessary complexity, jargon, formality, multisyllable words, and meaningless introductory phrases
	Use common words
	Describe medications named
	Avoid emphasis such as bold letters, italics, and underlining
	Avoid conclusory words such as "clearly" or "obviously"
Brevity	Plan the report to determine what is necessary
	Omit unnecessary words, sentences, paragraphs, data, and conclusions
	Edit ruthlessly to achieve briefest report that addresses the legal issue
Humanity	Refer to people by their names, not as impersonal nouns such as "defendant"
	Use quotations to give voice to persons interviewed and demonstrate attention to each person's perspective
	Avoid pejorative language

- Dangerousness determination after insanity acquittal—for disposition, locus of care, special management concerns
- Presentence evaluation—presence of mental disorder and need/value of treatment (Ciccone and Jones 2011)

The specific questions to be addressed in these evaluations are described in state and federal law, and the evaluator needs to be familiar with statutory requirements. The contents of reports for federal court are detailed in 18 USC §4247, and there are unique elements in U.S.C. for these various types of evaluation (Johnson et al. 2011).

Each of the above, except the competency evaluations, will generally include a description of the offense (alleged or adjudicated); this description is required in criminal responsibility evaluations. The competency evaluations are generally evaluations of present state of mind and court-relevant functional abilities. Evaluation of competency to confess is an exception, as this is usually conducted retrospectively in response to an attempt to suppress confession evidence. Diagnostic formulations are generally not necessary in competency reports, but a diagnosis will usually be provided as part of the other types of criminal evaluations.

Report writers should avoid including the defendant's account of the offense in the same section as the mental status examination, even though both sets of data are derived from the interviews. The former is historical data, which will also be informed by collateral interviews. The latter describes present findings of the evaluator's formal examination of the evaluee.

In criminal evaluations, malingering must be considered by the evaluator, as the potential for conviction and punishment create external incentives for false presentations by the evaluee. Data and opinion about malingering should be segregated to the appropriate sections of the report.

The conclusion or opinion section of the report will specifically address the legal questions and the evaluator's reasoning in reaching the conclusions. It is here that the report writer explains "to the legal system how the specific manifestations of the mental illness affect or affected the subjects thinking, judgment, and behavior" (Ciccone and Jones 2011, 110).

CIVIL

There are many types of civil forensic evaluations that a forensic mental health professional might conduct (Recupero and Price 2011; AAPL 2015), each with its own special considerations for report writing. These include medical malpractice, psychic harm/trauma, employment-related evaluations (disability, fitness for duty, workers' compensation), civil commitment (including sex offender commitment), psychological autopsy, child custody, and numerous competence evaluations.

In medical malpractice cases, the expert will need to describe the standard of care applicable to the case in order to opine about a breach of the duty owed to the patient. This may require exploration of clinical practice guidelines, academic literature, accreditation and regulatory body standards, different schools of thought about treatment recommendations, common law, case law, and state statute (Meyer et al. 2010; Recupero and Price 2011).

A special element in psychic harm cases is the need to discuss what treatment the evaluee needs, with its projected costs and prognosis. As in malpractice evaluations, an opinion about causation of the injury is an important part of the report. Attention to prior functioning, the presence of personality disorders, and malingering is also vital to these evaluations (Ciccone and Jones 2010; Recupero and Price 2011).

Psychiatric disability reports address different questions depending on the entity requesting the evaluation and the circumstances (e.g., social security, workers' compensation, private insurance). In workers' compensation reports, evaluators need to attend to jurisdiction-specific criteria for disability. The rating of impairment, however, is most often derived from the American Medical Association's *Guides to the Evaluation of Permanent Impairment* (Gold et al. 2008; Granacher 2011). The *Guide* has two chapters relevant to forensic psychiatry—one on brain-based conditions producing impairment, the other on mental and behavioral disorders. Fitness-for-duty evaluations require comparison of the evaluee's function to the specific requirements of the job description, as well as to assessment of alternative causation and pre-existing conditions (Gold 2010). Special considerations are required in reports on professionals' fitness for duty or competence to practice, which may be conducted on behalf of state medical boards, health-care organizations, or a physician responding to investigation (Anfang et al. 2005; Janofsky 2011).

One of the notable distinctions about civil commitment evaluations is that they are often conducted by treating psychiatrists, and this exception is noted in the AAPL Ethical Guidelines (AAPL 2005; Pinals et al. 2011). Another notable exception is that the civil commitment "report" is usually made in the form of a petition or court-provided template, and sometimes is not required in favor of testimony alone. The evaluator generally needs to opine about the presence of mental illness (as defined in the jurisdiction) and the nexus between the illness and the jurisdiction's criteria for civil commitment (usually harm to self or others, or grave disability; Pinals et al. 2011; Pinals and Mossman 2012).

Sex offender commitment reports are a variant of civil commitment reports by virtue of the decisions of the U.S. Supreme Court confirming the civil nature of these proceedings. It is possible, however, to conceptualize these evaluations as criminal in practice, as in the AAPL Practice Guideline on the Forensic Assessment (AAPL 2015). The criteria for commitment addressed in the report will adhere closely to the wording of the relevant statute or case law in the jurisdiction (Pinals et al. 2011).

Child custody reports are very complicated in that they require interviews of each parent (or other caregiver) and each child, and evaluation of the interactions between them. The expert must also document the background histories of each of these individuals, which creates the need for unique organizational structures that help the reader make sense of

a large amount of data (Ash 2011, table 12.1). The multiple sources of data present challenges to the report writer in giving voice to the narratives of the various, and often competing, parties, including the child (Steinberg and Fromm 2012). The evaluator makes custody recommendations according to jurisdiction-specific tests, which are usually some variant of "best interests of the child." (See Ash 2011, table 12.2, for a list of factors comprising the evaluation of best interests.) The child custody evaluation is also unusual in that the evaluator often offers a plan for custody and its related contingencies, which when well-crafted may lead to the settlement of highly contested matters (Ash 2011).

Competence reports address questions specific to a particular capacity or task, of which there are many examples (see Recupero and Price 2011, table 9.2). There may be jurisdiction-specific criteria in statute or case law for the various capacity determinations. For some of these, such as guardianship, there may be templates developed by the state for the report structure (Recupero and Price 2011). The American Bar Association and American Psychological Association (ABA and APA 2009) have outlined nine elements of capacity assessments, which should be addressed in competence reports:

1. Legal standard(s) to be applied
2. Functional elements related to the standards
3. Diagnosis(es) related to the functional impairments
4. Cognitive functioning
5. Relevant psychiatric or emotional factors
6. The evaluee's values related to the decisions at hand
7. The risk of the situation at hand
8. Means available to enhance capacity
9. Clinical judgment of capacity

The inclusion of diagnoses may be necessary and appropriate to many civil and criminal reports. The forensic evaluator also needs to bear in mind that describing the phenomenology of the psychological and behavioral circumstances (and the effect of these on the evaluee's functioning as it relates to the legal question) is generally more important for medico-legal purposes than enumerating the diagnoses per se (Allnutt and Chaplow 2000).

SPECIAL ISSUES

Psychological testing

The findings of any psychological testing conducted by a colleague are summarized in the data section of the report. The full report may be appended to the report, or submitted separately by the consulting psychologist. The forensic psychiatrist who is skilled in the administration of some psychological tests or assessment instruments, which has recently been encouraged as a way to strengthen forensic practice (Scott 2013), may do more than summarize the results in the report. The psychiatrist in that situation needs to know the limits of any test employed as well as its psychometric properties (Baranoski 2011). Psychological testing results can be used to identify levels of capacity or dysfunction, clarify diagnoses, assess malingering, buttress the forensic opinion, and identify areas of weakness in an evaluation requiring further data collection or other considerations (Baranoski 2011). Conflicts between the psychological findings and emerging psychiatric opinion need to be resolved before preparation of the report (Baranoski 2011).

Reasonable medical certainty

Although it is common for forensic mental health psychiatrists to offer opinions in written reports and testimony to a reasonable degree of medical certainty, this is a term without a precise definition—either in the law or in psychiatry. The term is commonly used to mean more likely than not, but some courts have required a standard approaching complete certainty (Leong et al. 2011). Jonas Rappeport described it as "that level of certainty which a physician would use in making a similar clinical judgment" (Rappeport 1985, 9). Leong and colleagues have attempted a synthesis of explanation of the term from the views of Seymour Pollack, Bernard Diamond, and Jonas Rappeport: "collection of an adequate database to answer the forensic psychiatric question at issue, considering the validity and reliability of the various data points (including vigilance for data distortion due to malingering, dissimulation, and/or exaggeration of history or symptoms), and arrival at the forensic psychiatric opinion through a reasoning process that includes consideration of alternative hypotheses and the reasons behind the ranking of the opinions considered" (Leong et al. 2011, 232). Report writers are advised to consider what they mean by using this term in any particular case and how they might answer questions about its use in their report. Buchanan and Norko have noted that it remains to be seen whether a consistent definition for this term can be attained. They suggest that the way forward may entail future descriptive research and the efforts of professional organizations to articulate guidelines addressing the level of confidence indicated by the term and the best way of describing it in reports and testimony (Buchanan and Norko 2011b).

Malingering

The *DSM-5* notes that malingering should be "strongly suspected" in any combination of four factors, each of which is commonly encountered in forensic practice: medico-legal context; discrepancy between claimed stress or disability and objective findings; lack of cooperation during a diagnostic evaluation; and antisocial personality disorder (APA 2013, 727). The evaluation of malingering is an important element of many types of criminal and civil forensic reports where the evaluee may be feigning symptoms or dysfunction (Scott and McDermott 2011). Malingering must be differentiated from factitious disorder, conversion disorder, and other somatoform disorders (Scott and McDermott 2011). As noted above, psychological testing can be a useful

adjunct to clinical interview and review of records in assessing malingering (Baranoski 2011). Ethics considerations about confidentiality warnings to evaluees when malingering is suspected can present challenges for the accurate collection of data. Scott and McDermott note that evaluators take different approaches to such warnings. They offer the suggestion of advising the evaluee that it is important to answer questions as accurately as possible (Scott and McDermott 2011, 244).

Quality improvement

There is relatively little research available on the quality of forensic reports (Wettstein 2005, 2010a; Goodman-Delahunty and Dhami 2012), but recent efforts in this direction may demonstrate a welcome trend (Robinson and Acklin 2010; Nguyen et al. 2011; Duits et al. 2012; Fuger et al. 2014). Studies generally demonstrate that essential elements are often missing in various types of forensic reports (Wettstein 2005; Robinson and Acklin 2010). Work to improve the quality of forensic reports is challenging, with a major barrier being the need to define the quality of forensic evaluations (Wettstein 2005). Efforts in that direction have involved analysis of content elements of reports against a checklist or evaluation instrument (Witt 2010; Duits et al. 2012). Fuger and colleagues recommend self-monitoring against such checklists as a way to improve the quality of reports (Fuger et al. 2014). The literature is mixed as to whether short-term training improves report quality (Robinson and Acklin 2010). Other methods suggested for improving the quality of forensic reports are peer review, credentialing, system-wide assessments, and feedback from users (Wettstein 2005; Nguyen et al. 2011; Duits et al. 2012; Buchanan et al. 2016).

Research needs

Improvement in forensic report writing is thus an area ripe for empiric research, including the effects of training and professional guidelines on report quality. Further developments in synthesizing professional ethics and the effectiveness of various methods of conveying narratives are also open to future research (Buchanan and Norko 2013). Advances in defining quality in forensic reports will benefit from more sophisticated analysis utilizing information and decision-making theories (Goodman-Delahunty and Dhami 2012). These approaches put our field on notice that not all information in a report will be considered by triers of fact and other decision makers, and that decision makers rely on simple and heuristic strategies that do not entail a rational weighing of all the available information (Goodman-Delahunty and Dhami 2012). The implications of this literature for forensic practice and report writing are profound. Yet there is no existing research on how information representation in forensic reports influences legal decision making. Future study is needed to investigate what information should be included, the placement and emphasis of information, and the optimal length of reports (Goodman-Delahunty and Dhami 2012).

SUMMARY

The care with which an expert prepares a forensic report reflects on the care with which the evaluation was performed and is directly related to the utility and success of the expert's contribution to the legal matter at hand. The evaluator also demonstrates professionalism in the report by attention to confidentiality, ethics, and humanism. Careful preparation for the evaluation and the writing of the report are critical to the quality and effectiveness of the final report. There is general consensus in the literature about the structure and content of various types of reports, although evaluators should exhibit flexibility in tailoring each report to the needs of the individual case. The evaluator reflects knowledge of the appropriate legal questions, standards, and jurisdictional laws in the way in which the report is constructed and the opinions justified. Experts may wish to investigate the use of checklists to improve the quality of their own reports. Many aspects of the effect of the information and the manner in which it is presented in reports upon legal decision making are currently untested empirically, and forensic psychiatrists are encouraged to participate in, and stay abreast of, such future research efforts.

SUMMARY KEY POINTS

- The written report is a central element of forensic practice and its most visible benchmark.
- The report should reveal the highest levels of professionalism in the execution of the work.
- Good reports require thorough evaluation and careful preparation.
- Report structures and content follow generally accepted formats but are tailored to the legal needs of individual cases.
- Quality improvement in report writing involves training, self-monitoring, peer review, professional guideline development and future research.

Guidelines for courtroom testimony

PHILLIP J. RESNICK AND JENNIFER L. PIEL

INTRODUCTION

The role of the expert witness is to educate the court about matters that are beyond the layperson's understanding. A key role for forensic psychiatrists is to provide expert testimony at depositions, trials, hearings, and administrative proceedings. Medical and mental health specialists are the most common category of experts to testify in federal civil trials, making up more than 40 percent of experts (Kafka et al. 2002). Psychiatrists make up nearly 4 percent of testifying experts in civil cases, more than any other specialty, except surgeons. Similarly, in criminal trials, psychiatrists have a vital role in a variety of evaluations such as competency to stand trial and criminal responsibility. In *Ake v. Oklahoma* (1985, 83), the U.S. Supreme Court discussed the "pivotal role" that psychiatry has come to play in criminal proceedings: "to conduct a professional examination on issues relevant to the defense, help to determine whether the insanity defense is viable, to present testimony, and to assist in preparing the cross-examination of the state's psychiatric witness."

TYPES OF WITNESS

All psychiatrists have expertise in the field of psychiatry, but the mere act of testifying does not mean the psychiatrist is an expert witness. There are two types of witnesses: fact (percipient) and expert. *Fact witnesses* state their direct observations. For example, a psychiatrist who saw a patient for psychological symptoms after an automobile accident might be asked to testify about the presenting complaints, number of visits, and any medications prescribed. A psychiatrist is not ordinarily asked to give opinions when serving as a fact witness. In a small minority of jurisdictions, however, the court may ask a treating psychiatrist to state an opinion. The psychiatrist should then be qualified as an expert witness and may seek an expert witness fee from the party who sought the opinion (Hirsch 1975). The opinions of treating psychiatrists may be given high credibility by the court because they are not the views of hired witnesses.

Expert witnesses have "special knowledge" of the subject on which testimony is to be given. The knowledge must be viewed as not normally possessed by the average person and beyond direct observation. Experts may express opinions that have legal significance, such as causation for a litigant's psychological harm or mental skills required to be competent to stand trial. In practice, psychiatric expert witnesses may function to make the judge aware of the facts, as well as their conclusions about symptoms, causation, and prognosis.

TRUTH, ADVOCACY, AND ETHICS

In the United States and England, trials are conducted within the adversary model—that is, the attorneys are advocates of the causes they represent. Despite the adversarial nature of the legal process, testifying psychiatric experts should resist acting as an advocate for a party to the case (American Academy of Psychiatry and the Law 2005). Two models have been proposed regarding the role of advocacy from testifying experts: the advocate for truth model and the honest advocate model (Gutheil 2009). In an *advocate-for-truth model*, the expert strives for objectivity and absolute truth in delivering testimony. In the *honest-advocate model*, the expert may be a persuasive advocate after coming to his or her opinion, but remain truthful in delivery of information. In contrast, a consulting (nontestifying) expert may assist legal counsel with the preparation of their case (Martindale and Gould 2011).

It is a fallacy to assume that a psychiatric witness can be completely impartial. Regardless of whether one is employed by the court or by an attorney, the psychiatrist usually starts out with an impartial attitude. Once experts form an opinion, however, it is only human for them to identify themselves with that opinion and to hope for the success of the side that supports their conclusions (Diamond 1959; Candilis et al. 2007). Experts may advocate for their opinions. However, once on the witness stand, experts must do their best to impartially preserve the truth and their professional integrity. Relevant information may not be kept secret (Candilis et al. 2007).

Blatant advocacy is easily recognized and reduces the credibility of the expert witness; subtle advocacy or bias (which could include unconscious bias) is the more difficult problem (Goldyne 2007). Zusman and Simon (1983) reviewed examinations of plaintiffs about psychological damage resulting from the 1972 collapse of the Buffalo Creek dam. They attributed differences in psychiatric opinions to the interview settings, the examiners' training and orientation, and identification with the attorneys who employed them. Psychiatrists must guard against any sense of loyalty to the retaining attorney that would cause them to shift their thinking from that of an objective expert witness to that of an advocate (Gutheil and Simon 2004).

A psychiatrist's diagnoses and conclusions regarding legal issues are considered only as opinions. Juries are instructed to decide for themselves how much weight to give the testimony of each witness. Even when it is uncontradicted, the jury has the right to disregard psychiatric opinion evidence. The trier of fact makes the ultimate decisions about disputed issues, such as criminal responsibility or liability for malpractice.

The expert should not go beyond the available data or the scholarly foundations of his or her testimony (Gutheil 2009). Ethical psychiatric experts can enhance their credibility by appropriately acknowledging facts of the case which are unfavorable to their opinion, the limitations of their opinion, and hypothetical situations under which their opinion would be different.

PREPARATION FOR TESTIMONY

When approached to form an opinion for a legal case, psychiatrists should request the specific legal issue and legal standard in writing by the attorney. In a criminal case, the attorney, for example, may wish an opinion about competency to stand trial, sanity at the time of the act, or psychiatric factors for mitigation of the penalty. Legal standards vary by jurisdiction. Before accepting any legal referral, psychiatrists should be certain that there is no actual conflict of interest or even an appearance of conflict of interest. Fees should also be clearly understood.

Before beginning an evaluation for legal purposes, the psychiatrist has an absolute obligation to inform the evaluee about any limitations of confidentiality and to specify those persons who will receive copies of any report. Psychiatrist–patient confidentiality by treating psychiatrists may or may not be respected in court. A treating psychiatrist may request an opportunity to explain to the judge in chambers why certain information may be irrelevant to the issue at hand and should remain confidential. The judge, however, is the final decision maker. The psychiatrist who complies with a judge's direction to reveal information is immune from criminal and civil liability. Should the psychiatrist fail to comply, the psychiatrist may be held in contempt of court.

DEPOSITIONS

A deposition is a sworn oral statement for legal purposes, usually taken outside of court. Depositions are of two types: evidence and discovery. *Evidence depositions* are taken to preserve testimony in the event that a witness will not be available at the trial. This type of deposition adheres to the usual trial procedures of direct and cross-examination, and is often videotaped for viewing at the trial. In a videotaped deposition, the psychiatrist should think of the camera as a friend. Each question and answer should be treated as a separate item because the deposition may be edited before it is shown at trial. Turning away from the camera is glaringly obvious on videotape.

Discovery depositions are designed to gather information prior to trials. Almost all questions are asked by opposing counsel. This type of deposition plays an important role in civil litigation. The psychiatric expert should thoroughly prepare for a discovery deposition because it is likely to have a significant impact on settlement negotiations. Over 90% of cases settle before trial.

During a discovery deposition, the attorney's goals are to learn the facts and opinions of the opposing witness, assess strengths and weaknesses, and gather ammunition for cross-examination at trial. The attorney may ask broad questions to encourage rambling answers that might reveal new facts. The expert witness should not volunteer any information not called for in the questions. The psychiatric expert should listen carefully to each question asked during the deposition. It is helpful to pause for a moment after the question is asked to give it careful consideration, and to allow time for other attorneys to object (Gutheil 2009). The expert witness should request the written record or audio or video recording of the deposition for future review and planning of trial testimony. One's deposition should be reviewed prior to trial to refresh the expert's memory. Attorneys often seek to impeach the expert's credibility by showing differences between deposition and trial testimony.

COURT TESTIMONY

Psychiatric expert witnesses first undergo direct examination by the attorney who called them. This consists of nonleading questions to obtain the witness's opinions and reasoning without interference.

Cross-examination is conducted by the adversary attorney to test the credibility of the testimony. Redirect examination—sometimes called rehabilitation—allows the retaining attorney to repair damage and clarify points from cross-examination. Re-cross-examination is limited to issues raised in the redirect examination.

DIRECT EXAMINATION

Qualifications

At the beginning of the direct examination, the credentials of the expert are elicited. The retaining attorney asks questions

to demonstrate the witness's credibility and to qualify the witness as an expert. Ordinarily, any licensed physician will be recognized as an expert witness. Qualifications should include schools attended, internship, residency training, academic titles, hospital affiliations, board certifications, and honors. The expert's publications that are especially relevant to the case at hand should be mentioned. It is preferable to have the attorney elicit these qualifications through several questions to avoid the appearance of immodesty (Usdin 1977). After eliciting the expert's qualifications, the attorney proffers the witness as an expert. The opposing attorney may accept the witness's qualifications; alternatively, the opposing counsel may challenge the witness's background or methodologies for his or her opinion in a process called *voir dire* ("to speak the truth"). Ultimately, the judge decides whether the witness may testify as an expert.

Credibility

It is critical for the expert witness to establish credibility with the jury. Credibility may be divided into three components: (1) expertise, including the witness's credentials, training, and experience; (2) trustworthiness, including sincerity, the appearance of objectivity, and lack of partisanship; and (3) dynamism—that is, the style of delivery during testimony (Bank and Poythress 1982).

Trustworthiness may be more important than credentials in achieving credibility (Appelbaum and Anatol 1974). People judge one another on the basis of traits that may have no relation to actual trustworthiness, such as physical characteristics (Spellman and Teeney 2010). Wearing conservative executive-style clothing increases the psychiatrist's credibility in court. Male psychiatrists should wear dark suits. Solid colors enhance credibility, whereas pinstripes confer greater authority (Malloy 1988). Female psychiatrists appear most credible if they wear solid-colored suits with skirts that fall below the knee. Conservative dresses with contrasting blazers are also effective (Malloy 1996). Both male and female witnesses should avoid jewelry or anything ostentatious. Local customs should be considered in making decisions about what to wear to court.

The expert witness's style of speech has considerable impact on the expert's credibility (Lubet and Boals 2009). In controlled studies of mock testimony, *powerful* speech was found to be more convincing and credible than *powerless* speech (Conley et al. 1978). Powerful speakers are straightforward and give more one-word answers than powerless speakers. Used by persons with low power and status vis-à-vis the court, powerless speech tends to make more frequent use of the following (Erickson et al. 1978):

1. Intensifiers (so, very, surely): I surely did.
2. Hedges (kind of, I think, I guess).
3. Especially formal grammar.
4. Hesitation forms (uh, well, you know).
5. Gestures (using the hands to point while saying "over there").
6. Questioning forms (rising, question intonation in declarative contexts).
7. Excessive politeness (please, thank you, sir).

Opinion with reasonable medical certainty

After listing their qualifications, experts are next asked to describe their clinical examination and the background materials that were reviewed. It is most efficient if the witness can refer to the first page of their report for the exact dates and length of examinations and a complete list of documents reviewed.

Witnesses are then asked whether they have formed an opinion regarding the contested issue. Psychiatrists should render their opinions to a reasonable degree of medical certainty (Leong et al. 2011). The exact definition of "reasonable medical certainty" varies from one jurisdiction to another (Miller 2006). In most states, it simply means more probable than not. Psychiatrists should ask the retaining attorney to explain the exact meaning of the phrase in a particular case if they are not certain.

In law, there is a distinction between the words *possibility* and *probability*. The law considers anything possible. However, something is not probable unless it is more likely than not. In other words, when mathematically expressed, its chances are 51% or greater (Hirsch et al. 1979). The expert should be aware that "reasonable certainty" is simply the minimum level of confidence required to express an opinion in court. It is possible for the expert who is more confident to say so (Lubet and Boals 2009).

When experts are asked whether they have formed an opinion with reasonable medical certainty, they should reply with only a "yes" or a "no." According to courtroom ritual, the witness may not offer an actual opinion until asked. The witness is then asked to explain the basis for the opinion—that is, the underlying data and step-by-step logic used to reach the conclusion. Narrative direct testimony has been found to be effective in conveying information to the trier of fact (Commons et al. 2010). The presentation should be punctuated by some questions, however, since prolonged, uninterrupted narrative may become tiresome.

Hypothetical questions

Hypothetical questions may be put to the expert witness on direct or cross-examination. Traditionally, an expert could express an opinion only if it were based on personal knowledge, a hypothetical, or a combination of these. Accordingly, attorneys used hypothetical questions to focus the jury to the key facts that supported the expert's opinion. Hypothetical questions permit the jury to know the premises that underlie the expert's opinion, enabling proper evaluation of its weight.

The modern approach, including the Federal Rules of Evidence (703, 704), has liberalized the sources of information that experts may rely upon in formulating their opinion. It is not improper for an expert witness to give an

opinion without having performed a personal examination. However, the psychiatrist must have made an effort to perform a personal examination when appropriate based on the nature of the case. Both in the psychiatric report and on the witness stand, experts should state that their conclusions are limited because of the inability to perform a clinical psychiatric evaluation. The only limitation on the supporting data used by experts is that it be the type reasonably relied on by experts in forming opinions.

Hypothetical questions are used by retaining attorneys to elicit information or predictions based on underlying interpretations of facts. During cross-examination, hypothetical questions may introduce evidence that was previously unavailable to the expert witness. The appearance of a closed mind about new data suggests partisanship. One fair answer is, "I would need to re-evaluate the subject based on the new information." Opposing counsel may use hypothetical questions to make the expert assume facts that are incongruent with their conclusions or opinions (Brodsky et al. 2012). Although theoretically sound, in practice hypothetical questions often prove cumbersome and confusing to juries. The record for length was set in a 1907 Massachusetts "will" contest with a 20,000-word hypothetical question that took several hours to read. The answer was, "I don't know" (MacDonald 1976).

Suggestions regarding direct examination

During the pretrial conference, the attorney and the expert witness should plan to explicate those issues on direct examination that are most likely to be attacked during cross-examination. This provides an opportunity to fully explain problematic areas to the jury, without the constraints of cross-examination. In any event, redirect examination should allow the expert witness to explain issues that were cut short during cross-examination.

Answers to specific questions should be relatively short, clear, and stated in simple language. If answers are overqualified, boredom can cause the jury to lose interest. Generally speaking, the "homier" the analogy, the better it is. While attempting to stay within these guidelines, expert witnesses must still behave naturally for their own personalities. A stilted performance will detract from the witness's appearance of sincerity.

Psychiatrists should use demonstrative evidence if possible. Demonstrative evidence should be distinguished from substantive evidence, which include objects or materials that played a role in the incident at issue (e.g., murder weapon, x-ray). Demonstrative evidence may be referenced by the expert without formal admission into evidence. However, legal counsel may proffer it as part of the witness's testimony so that it can be taken into the jury deliberation room. Visual aids useful to psychiatrists may include charts or graphs, lists of key points of the expert's opinion, and video recordings. A graph showing a decrement in IQ, for example, may facilitate the jury's understanding of the seriousness of a head injury.

Expert witnesses should ordinarily look at the jury and direct their remarks to them. Eye contact will help the psychiatrist assess the jury's understanding of what the expert is saying and enhance the expert's credibility. The expert witness should never talk down to jurors—if jurors feel patronized, they will not accept what the witness is saying.

The expert witness must not become, or even appear to become, an adversary. The appearance of impartiality is best achieved when the witness treats both lawyers (on direct and cross-examination) with the same professional courtesy and distance (Curran et al. 1980).

Psychiatrists should not use professional jargon in court because it is likely to be misunderstood, not understood, or made to look ridiculous. It is preferable to use equivalent words, such as mood for affect, even if they are not perfect synonyms. Emerson observed that "eloquence is the power to translate a truth into language perfectly intelligible to the person to whom you speak" (Emerson 1876).

The following example of psychiatric testimony contains jargon: "The patient showed marked psychomotor retardation and considerable inhibition of speech. Some ideas of reference were implied, although no frank delusion formation was evident." This could be expressed in lay language as follows: "His movements were slow and his voice was low and monotonous. He spoke little and volunteered nothing. He felt that certain people were referring to him when they spoke with each other privately, but he did not show any clear-cut delusions about this—just vague ideas that he was the subject of other people's conversations" (Davidson 1965).

Nothing alienates a jury more quickly than a psychiatric expert witness who appears arrogant. An attorney may ask expert witnesses whether they have ever been wrong; experts should reply "yes," assuming it is true. While testifying, witnesses should attempt to display dignity, confidence, and humility.

Ordinarily, the expert witness should not attempt to be humorous; a trial is a serious matter. Self-deprecating humor is the safest type. An extremely experienced witness may attempt to use humor as a way of coping with an overzealous cross-examiner, but this is certainly not recommended for the novice.

The expert witness's answers should not go beyond the questions in direct or cross-examination. Volunteering additional information may open up new areas for cross-examination, which could be highly damaging. Similarly, psychiatric expert witnesses should be familiar with the ultimate issue rule. Historically, courts limited experts from testifying as to the ultimate issue, or the specific question that is before the trier of fact. This has largely been rejected for most types of expert testimony in Federal Rule of Evidence 704. Under Rule 704(b), however, an expert may not testify in federal court to the ultimate issue when a criminal defendant claims a mental state defense. Many state courts do allow testimony on ultimate issues related to mental state or culpability.

It is usually best for psychiatric expert witnesses not to volunteer their theoretical orientation. A theoretical school can easily be attacked on cross-examination.

Expert witnesses should not say that they have an impression, feeling, or speculation (Boccaccini 2002). If the psychiatrist believes that something is more probable than not, the same information can be communicated by calling it a professional opinion.

The expert witness should never mention the presence of a defendant's insurance company in a civil trial. In most jurisdictions, this is viewed as prejudicial because it may encourage the jury to increase the amount of money awarded to the plaintiff. Consequently, mention of an insurance company could lead to a mistrial.

Whether expert witnesses should mention counterarguments to their own position during direct examination is open to controversy. The opposing attorney will be more than happy to raise negative points during cross-examination. One approach is to directly address the counterarguments or negative points. This highlights the expert's fairness and allows the retaining attorney to present the information in the light most favorable to the attorney's client. If no rebuttal is expected, persuasive impact is reduced by bringing up counterarguments. This may, however, raise ethical issues about whether the witness is then "telling the whole truth."

Table 5.1 Common areas of cross examination

1. Qualifications
2. Compensation
3. Hired gun
4. Professional reputation
5. Professional/philosophical bias
   - Types of cases in expert role
   - Views on treatment versus punishment
   - Views on crime and punishment
6. Personal bias
   - Victim of crime
   - Relationship with attorney
   - Relationship with litigant
   - Race/culture/gender
7. Knowledge of relevant facts
8. Knowledge of relevant legal standard
9. Knowledge of relevant literature
10. Methods used in forming opinion
11. Inconsistencies
    - Internal inconsistencies from the witness
    - Inconsistencies with other documents/testimony
12. Soundness of opinion
13. Skeletons in the closet

CROSS-EXAMINATION

Areas of attack

Cross-examination is the questioning of a witness by a party other than the one who called the witness. Cross-examination is limited to the scope of testimony from direct examination, but this may be liberally construed. The purpose of cross-examination is either to discredit or clarify testimony already given.

The cross-examiner may seek to discredit adversary testimony by showing the witness to be a fool, a liar, and a nitwit. The goal of cross-examination is not to convince witnesses of their errors, but to point out a case's weakness that might not be evident to the trier of fact.

The cross-examiner may seek to attack the expert witness in the following areas: *credentials*, *bias*, *adequacy*, and *validity* (Table 5.1). The credentials of an expert witness may be attacked by showing a lack of experience or education. A cross-examining attorney may bring out the fact that an opposing expert witness has not achieved board certification or has required more than one attempt to do so.

The amount of testimonial experience may also be used to discredit an expert. The cross-examiner may imply that the witness is inexperienced and unknowledgeable because of limited testimonial experience. Conversely, if a witness does have substantial testimonial experience, the cross-examiner may try to show the witness to be a professional "hired gun." If the witness is asked whether or not he or she is a professional witness, one good answer is, "my profession is the practice of psychiatry. It just so happens that I am frequently asked to testify on psychiatric issues."

Bias in the expert witness may be demonstrated by showing a history of having always been employed by one side. The appearance of bias or personal interest is decreased when witnesses are able to say that they have testified on behalf of both prosecution and defense, or have testified on behalf of both plaintiffs and defendants in civil cases. A cross-examining attorney may also attempt to show bias by questioning about fees or pretrial conferences. The expert should not try to avoid answering these questions. If asked how much one has been paid for one's testimony, the expert may reply, "I'm not being paid for my testimony. I'm been paid for my time, like the other professional people in the courtroom." Similarly, the expert should not feel embarrassed about admitting to having a pretrial conference with an attorney, because this is necessary to prepare for testimony.

The psychiatrist's examination may be attacked as being inadequate. Issues such as examination length, privacy, or obtaining corroborating information may be questioned. A brief examination may be portrayed as being inadequate to "fully understand" a complex matter. A cross-examiner may attempt to demonstrate inconsistencies between police accounts and the defendant's account given to the psychiatrist. Marked inconsistencies may make the psychiatrist look gullible and make the defendant look guilty. A cross-examiner may seek to demean the psychiatric examination

by asking, "Do you mean to say that all you did was talk to the plaintiff?" A good response is to say that psychiatrists have special training in evaluating mood, thought organization, and speech patterns of persons with mental illness. The routine mental status examination may be described as a series of tests to assess such items as memory, concentration, abstract thinking, and judgment.

The validity and reliability of all clinical examinations may be attacked. Faust (2011) described the limited reliability of psychiatric examinations. Research demonstrated that different theoretical backgrounds predispose psychiatrists to reach different conclusions based on the same data. There is no scientific evidence indicating the validity of a retrospective diagnosis. Attempts should not be made to defend the science of psychiatry; rather, the expert should state that he or she is confident of his or her opinion in this particular case. The cross-examiner may point out inconsistencies within an expert's report, between the expert's current testimony and previous testimony, and between testimony and published articles. Experts should be aware that attorneys may search the Web or subscription Internet databases for an expert's professional biography, publications, and even prior testimony (Coggins 2005).

Psychiatric expert witnesses should be aware that transference feelings toward cross-examiners, opposing experts, or judges may diminish the effectiveness of their testimony. The primary danger is overadvocacy. If a witness becomes partisan, the witness is likely to become overextended, emotional, and defensive, thereby losing credibility.

Types of cross-examiners

The expert witness should be prepared to encounter three particular types of cross-examiners (Bromberg 1969). The first is the "country" lawyer who claims to know nothing. He or she stumbles over technical words, and seeks to oversimplify human actions and reduce the psychiatrist's explanations to meaningless gobbledygook for the jury. A good response for the psychiatrist is to "one down" the attorney. For example, the psychiatrist might say, "I understand what you mean about big words; I often have difficulty understanding legal terms." This gambit places the expert witness back on the same level as the jury.

The second type of cross-examiner is the "unctuous" lawyer who is excessively polite. He or she apologizes for taking up the doctor's valuable time and refers to the witness as a "man of science." By concealing certain information, such a cross-examiner may proceed to set the psychiatrist up for a devastating blow toward the end of his or her testimony. Thus, it is particularly important for the experts not to let their guard down when the cross-examiner is especially friendly or flattering.

Finally, the "blustery" cross-examiner works toward immediate destruction of credibility and attempts to bully the witness by making reference to the psychiatrist's fee and loyalty to the retaining attorney. By remaining calm, the expert's polite demeanour will look favorable to the jury.

Suggestions regarding cross-examination

An expert witness should never be a smart aleck or argue with a cross-examiner. The jury will ordinarily identify with the witness; but if the witness acts smart, the jury will take the side of the cross-examiner in the belief that he or she is just doing his or her job.

Psychiatrists should not be defensive during cross-examination. Witnesses need not be apologetic if cross-examiners do not agree with their opinions. It gives the cross-examiner a distinct advantage when witnesses lose their temper because it makes any witness look overinvolved to the jury.

The expert witness should never guess at an answer; it is better to say that one either does not know or does not remember. An expert witness is not expected to have a quick, knowledgeable reply to every question.

During cross-examination, the expert should graciously concede points and admit the obvious. For example, when asked, "Dr., isn't it possible…," the expert should reply, "Of course it is possible." However, the expert may then go on to point out why it is unlikely. Refusing to concede an obvious point causes the expert to look either foolish or hostile. After the expert's testimony has concluded, and neither attorney has any further questions, the judge will dismiss the expert. The psychiatric expert should then leave the courtroom. The expert should not stop to consult with the retaining attorney, or linger to see the remainder of the trial. These activities suggest too much interest in the final outcome of the trial (Gutheil 2009).

The psychiatric witness should be aware that any files that are taken to the stand may be scrutinized by the cross-examining attorney; the witness may even request a recess to review them in detail. Consequently, if the psychiatrist does not wish to be cross-examined on certain information, it should not be taken to the witness stand.

The expert witness should be wary of acknowledging any book as an authority (Imwinkelried 2012). Once a book is acknowledged, the witness may be cross-examined on all of its contents. Instead, the psychiatrist might indicate that his or her knowledge comes from many sources, including training and experience, rather than any single textbook. Before responding to any question about a quote, the expert witness should insist on seeing it in context.

The cross-examiner may ask the expert witness's opinion of opposing expert witnesses. It is unbecoming to engage in personal attacks, even if one has a low opinion of an opposing witness. It is better for experts to simply state whether they disagree with the opposing expert on this occasion.

CONTROL IN THE COURTROOM

A good cross-examiner will seek to control the witness. However, there are several ways in which the witness can exert some control during cross-examination.

The witness may pause before answering a question, which serves to break the rhythm of the cross-examiner's questioning (Boccaccini 2002). It also allows the retaining

attorney time to make an objection. The witness may further disrupt the flow of a cross-examiner's attack by refraining from answering any question that includes a minor error.

The expert witness should take opportunities to break eye contact with the cross-examining attorney in order to direct answers toward the jury. This serves to further establish the expert's role as an educator, as opposed to someone who is merely being questioned. The experienced expert may use cross-examination as an opportunity to reiterate opinions given during direct examination.

The expert should try to give full opinions during cross-examination. If interrupted, the expert should attempt to complete his or her answer. When the cross-examiner attempts to limit answers, the jury is given the impression that the attorney is trying to conceal something. When the expert is cut off before completing an answer, it should serve as a signal to the retaining attorney to explicate that area on redirect examination. In an effort to more tightly control the expert, the cross-examiner may demand only "yes" or "no" answers. The expert should listen closely to each question, and determine whether or not the whole truth will be conveyed by a "yes" or "no" answer. If it cannot, an appropriate answer might be "that question cannot truthfully be answered 'yes' or 'no'" (Gutheil 2009).

The expert should be alert to a pattern of questioning designed to elicit only "yes" answers. This technique, which is commonly used by salespersons, makes it more difficult for the expert to say "no" when the occasion arises. A cross-examiner may misquote an expert's report or earlier testimony. This type of error should be pointed out. It may be an innocent mistake, or a deliberate attempt to distort testimony. If an expert is badgered, the witness may turn to the judge and say that he or she has answered the question as well as he or she can. However, this option is best reserved for only extreme situations.

Finally, the expert should not appear vanquished if a point must be conceded. The witness should avoid conveying any nonverbal communication of defeat to the jury (Brodsky 2004).

RIGHTS OF WITNESSES

The expert witness has several rights in court (Danner 1983):

1. If the expert is unclear about how he or she should answer a question, or whether he or she must answer the question posed, the expert may ask the judge.
2. The expert may ask the judge whether the material asked for is privileged.
3. The expert may refuse to answer questions that he or she does not understand. The expert may also ask examining counsel to clarify or repeat the question.
4. The expert may state that he or she does not know the answer to a question.
5. The expert may ask the judge whether he or she can qualify the answer when a "yes" or "no" answer is requested.
6. The expert has a right to complete his or her answer, and should protest if interrupted.
7. The expert may refer to written records to refresh his or her recollection.

SUMMARY

The legal process should not intimidate the expert witness. The psychiatric expert possesses greater expertise in matters of mental health than the other courtroom participants. No professional undergoes more intense scrutiny than the psychiatrist who testifies in court. It takes courage of conscience for psychiatric experts to tell a retaining attorney that their opinion will not be helpful. The expert witness must be able to endure seeing his or her opinions deliberately distorted by a cross-examiner one day, and incorrectly reported by the press the next day. However, the expert who is knowledgeable, well prepared, and thinks well on his or her feet may find the courtroom experience an enjoyable challenge.

SUMMARY KEY POINTS

- The judge determines whether the witness has the necessary knowledge, skill, experience, training, and/or education to testify as an expert witness.
- Expert witnesses should prepare for testimony by reviewing their opinion, evaluation of the litigant, any deposition transcript or recording, and participating in pretrial meetings with legal counsel.
- Expert witnesses must articulate the basis for their opinion(s).
- On cross-examination, opposing counsel may seek to discredit the witness on topics of credentials, fees, bias, and methods used to formulate his or her opinion. Expert witnesses may be impeached on the bases of inconsistent statements.
- Expert witnesses have rights in court and can seek guidance from the judge on many procedural topics.

Practical issues in forensic psychiatric practice

ROBERT L. SADOFF

INTRODUCTION

The practice of forensic psychiatry can provide a satisfying and rewarding experience. However, it can also be very frustrating unless one pays attention to details that may significantly affect the work of forensic psychiatrists. Aside from all of the substantive materials that need to be incorporated in the practice of good psychiatry in legal contexts, forensic psychiatrists must also be good practicing clinicians.

An important difference between forensic psychiatry and general psychiatry is that forensic psychiatrists are investigators whose assessment must include information beyond the clinical examination—that is, all data relevant to the legal issue at hand. For example, in criminal cases forensic psychiatrists should obtain, at a minimum, the police investigation reports, the crime scene forensic data, witness statements, and the defendant's confession when available. In civil cases, forensic psychiatrists should review medical records of prior injuries, operations, or other traumatic experiences, as well as observations of others who have been involved in the care and treatment of the plaintiff. In sum, for forensic psychiatrists the clinical examination is necessary (when possible) but not sufficient for a complete and comprehensive assessment.

In discussing practical issues for forensic psychiatrists, it may be instructive to describe two different cases, one criminal and one civil, pointing out various areas that require observation and clarification.

CRIMINAL CASE

The first step in any case is the initial contact by the attorney to the psychiatrist. When a public defender or a private criminal defense lawyer requests consultation on a criminal case, several questions must be raised and issues clarified at that initial communication in order to avoid subsequent problems. First, the psychiatrist should ascertain the nature of the charges and the location of the defendant. Is the defendant at large—that is, on bail, or confined in a particular institution? The attorney should then be asked to give a brief synopsis of the case and the reason for seeking psychiatric consultation. If satisfied that it is the type of case on which the psychiatrist wishes to consult, then more information is obtained from the attorney (Sadoff and Dattilio 2008).

All available records should be provided at the initial mailing. The psychiatrist should be aware that various discovery rules in different jurisdictions may limit the immediate availability of some discovery material. What is important for valid assessments are the police investigation reports, the statement of the defendant if one has been made, and statements of other witnesses.

The timing of the examination of the defendant, depending on the nature of the case, may be an issue. If there is a delay between the crime and the request for psychiatric consultation, then there may be no urgency. However, some cases depend on a very early examination of the defendant, as close to the time of the commission of the alleged offense as possible. This may involve the psychiatrist traveling to the jail in the evening or on a weekend. Psychiatrists may also wish to conduct early interviews with other people such as the spouse, family members, and neighbors in order to obtain a clear picture of the event in question.

With respect to fees, the psychiatrist should clarify the requested fees with the attorney during the initial telephone call. In private criminal cases, working for the defense, a retainer fee is usually sent with the materials prior to the examination. For public defenders or prosecutors, billing procedures usually preclude retainer fees. However, the hourly fee should be agreed upon at the outset to avoid any later confusion. Some prosecutors and public defenders require contracts with their expert witnesses, and some forensic psychiatrists want that as well for their records so that there are no misunderstandings.

Depending on the wish of the psychiatrist or attorney, the defense attorney may be present at the initial examination. If the psychiatrist is examining for the defense, the presence of the attorney can help to introduce the psychiatrist to the defendant and to avoid problems where the defendant may not be certain whether to speak to the psychiatrist. It may ease entry to the institution by having the attorney present,

or by calling ahead to ensure admission. Generally, a court order or letter of introduction is required for admission to various facilities.

All prisons have security measures to ensure safety and may require a search of the psychiatrist before entering secure facilities. It is essential that the psychiatrist knows not to bring contraband into these facilities. All knives, matches, and gum should be left in the car or in the office. Recording devices, cellphones, and beepers are usually not allowed. The patient's records, a notebook, and pen or pencil for taking notes are allowed. Some facilities require the psychiatrist to lock away wallets, purses, keys, or other items in a safety locker before admission.

Examining the defendant

When meeting the defendant, it is important to reveal the identity of the psychiatrist, whom the psychiatrist represents, and what will be done with the information obtained from the defendant. This is essential, especially when working for the prosecution, so the defendant understands that the psychiatrist is not working for the defendant's attorney or to help the defendant and that what is told to the psychiatrist may be presented in a court of law and can be used against the defendant. It is also important to indicate to the defendant for what purpose the psychiatrist is seeing the defendant—that is, competency to stand trial, criminal responsibility, or evaluation for sentencing, including the possibility of the death penalty. In addition to being important ethically, without telling the defendant the purpose of the examination, the psychiatrist's testimony may later be restricted or may serve as a basis for appeal if there is a conviction (*Estelle v. Smith* 1981).

In some cases, defense attorneys may wish to be present when the psychiatrist is examining for the prosecution. That appears to be the right of the defendant in most jurisdictions, unless the court orders that no one else is to be present during the examination. In some cases, when the defense attorney is not present, the court may order the examination to be audio or video recorded. In some jurisdictions, the defendant need not cooperate with the prosecution psychiatrist (Purdons; *Commonwealth v. Campo* 1978; *Commonwealth v. Glenn* 1974). The defendant may be ordered to be present during the examination, but may not be ordered to speak to the prosecution psychiatrist. Thus, the examination may be limited or restricted, and that fact should be carefully noted in any written report. However, in some jurisdictions the defense may not put forward an insanity defense if the defendant does not cooperate with the prosecution psychiatrist as the defendant did with the defense psychiatrist (*New Jersey Statutes* 2CA–5C).

It should be noted here that it is unethical for a forensic psychiatrist to examine a defendant for the prosecution before an attorney has been appointed or retained (American Academy of Psychiatry and the Law 2005).

It is important to take a thorough and comprehensive history during the examination of the defendant. Sometimes, multiple examinations will be required before an opinion can be given. Occasionally, special testing such as psychological and/or neuropsychological testing, and neurological examination with electroencephalography (EEG), magnetic resonance imaging (MRI), or computed axial tomography (CAT) is needed. Where memory is impaired, a sodium amytal or hypnotic interview may be helpful. In such cases where hypnosis or amytal is utilized, the procedure should be video recorded. During such examinations, one should not lead the defendant or make undue suggestions to the individual whose memory is impaired. Such leading questions or suggestible influence will detract from the effectiveness of the examination and may result in an invalid conclusion.

Preparation of the report

The forensic psychiatrist should receive and review all discovery materials and all information that is necessary for forming an opinion regarding the defendant's competency, criminal responsibility, and/or disposition before rendering a report. Sometimes the court orders a report before all discovery has been obtained. In that case, the psychiatrist should indicate it is a preliminary report based on the order of the court, without the availability of all records that are known to exist. At the bottom of the report, the psychiatrist may write, "When other information is obtained or made available to me, I will review it, and if it affects my opinion, I will prepare an addendum or modification to this preliminary report." In that way, the psychiatrist duly satisfies the demand of the court while recognizing that limitations on the psychiatric opinion(s) may occur as a result of the rules of law within that jurisdiction. The psychiatrist also keeps the door open for additional materials that may or may not change the opinion(s) and result in an addendum to the report.

Some jurisdictions have an open discovery rule, whereby all information is freely given by both the prosecution and defense. In other jurisdictions, attorneys withhold information until the judge orders the release of the data. In one case, for example, the prosecution expert's report was not given until the morning he testified. It was very difficult to try to read through the 67 pages of his report in the few moments before the court opened and the expert took the stand. That appears to be an unnecessary burden and a deprivation of courtesy between and among the principals in the courtroom. How much better it would be if everyone had time to review, digest, appraise, and analyze the reports of other experts so that the examination and cross-examination can be as effective as possible. This "game playing" is a reflection of the adversarial nature of the proceeding. Some jurisdictions have eliminated that problem by having a much more cooperative approach, even within the adversarial system. Nevertheless, the forensic psychiatrist must be aware of the particular rules within each jurisdiction, as these may vary. One must not be caught off guard by assuming that the rules are similar everywhere.

Preparation of the expert witness

The preparation of the psychiatrist as an expert witness is essential. The psychiatrist should never go into the courtroom without first preparing with the attorney. One must not only prepare for the questions that will be asked on direct examination but must also anticipate the cross-examination.

Preparation also includes telling the attorney what the responses will be to various cross-examination questions. This is done so the attorney is prepared to rehabilitate on redirect. Sometimes, the response to a good cross-examination question will weaken the effectiveness of direct testimony. Some attorneys prefer their experts to argue with the cross-examining attorney to defend their weakened position. However, it is better for the attorney calling the expert into court to rehabilitate on redirect, rather than to expect the expert to be the one to deny information or to argue points on cross-examination. One should be an advocate for the attorney's position, because a case should not be accepted if the psychiatrist does not support that position, but not an adversary in the traditional sense.

The most important characteristic of the expert witness is credibility. Without credibility, there is no effective testimony. Cross-examination questions are often asked that go to the credibility of the expert witness. If the expert does not respond in a believable manner, the jury will have no faith in the expert and will discount other substantive opinions given.

It is important in criminal cases, when working for the defense, to receive in advance one's fee for time in court. "The check is the key to the courtroom door." The credibility of the expert is also enhanced by having received the fee in advance, as the expert is not dependent on the outcome of the case in order to receive the fee. On cross-examination, experts are often asked if they have been paid for their testimony. The response is that experts are paid for their time, and not for the testimony. Experts should not apologize for receiving an adequate fee for the time in court. The fee is always paid on an hourly basis, but in courtroom work there may be a minimum of four hours for a half-day or eight hours for a full day if the testimony goes into the afternoon session. The psychiatrist is not able to determine how many hours will be spent in court, and thus cannot schedule patients accurately. Therefore, it is advisable to clear at least a half day or perhaps a whole day, depending on the nature of the case, and then to charge the attorney accordingly. The fee should come from the attorney and not the client. The expert is the agent of the attorney, aiding the attorney who helps the client. Whatever arrangement is made between attorney and client is of no concern to the psychiatrist. The contract is with the attorney, not the client or defendant.

It is important for expert witnesses to know that they are not responsible for the ultimate verdict. Psychiatrists neither win nor lose the case: they are but one cog in the great wheel of justice, and should not boast upon winning a case, nor should they fear being blamed for losing one.

Testifying in court is a skill and an art. Experts must be well prepared with the facts and details of the case. It is helpful to have the materials that were reviewed listed in the report so that the expert can turn to the report and read off the materials that helped support the opinion given. Experts should have those materials available in a logical sequence in order to turn directly to the materials and not appear to be fumbling with papers on the witness stand. A disorderly stance only diminishes the image of the psychiatrist as a true professional in the eyes of the jury.

It is important to respond to cross-examination questions in a professional manner and usually with direct, short answers. Good attorneys usually do not ask "why" questions on cross-examination, since that would open the door for psychiatrists to explain the rationale for their conclusions. Usually, the cross-examination questions require short responses such as "yes" or "no." However, psychiatrists should not be bound to a "yes" or "no" answer if doing so would confuse the jury or make the testimony unclear. Experts can usually appeal to the judge to be allowed to answer the question and then offer a clarification. Nevertheless, if restricted to a "yes" or "no" answer, an expert must rely on the skill of the attorney calling the expert to rehabilitate on redirect by asking the expert to clarify the answer given on cross-examination. Psychiatrists must recall that this is a battle between lawyers and not between and among the experts. Psychiatrists may disagree with colleagues without being disagreeable. Expert psychiatrists should never indicate that colleagues are lying or incompetent, but rather disagree with their findings. A colleague may have conducted a more thorough investigation or have a different database, thus reaching a different conclusion.

CIVIL CASE

When called by the plaintiff's attorney in a civil case, the forensic psychiatrist should ascertain initially the nature of the case (e.g., competency, personal injury, toxic tort, malpractice, domestic relations matter) and determine whether the case is within the psychiatrist's expertise. It may be that the psychiatrist consulted is not a child psychiatrist or does not have sufficient experience with psychopharmacology or with the use of electroshock therapy, and the case may hinge on specific expertise in any of these areas. It is incumbent upon the professional to refer the attorney to the proper experts who could give the most effective assessment and testimony, if needed, in such a case.

In malpractice cases, it is important to determine initially who the defendants are and whether there would be any conflict of interest if the psychiatrist became involved either in a medical malpractice case for damages, or in a psychiatric malpractice case for liability and damages. It may be best to refer the plaintiff's attorney in some psychiatric malpractice cases to colleagues a fair distance away or in another jurisdiction in order to avoid any conflict of interest. If the psychiatrist agrees to accept a case for a civil defense attorney in a psychiatric malpractice case in which

the defendant is known to the expert, all such prior contact must be revealed at the outset. Defense attorneys may need to decide whether to allow the psychiatrist to become involved, as any prior contact may affect the case on cross-examination. Would the expert have a particular bias in helping a "friend" in court?

Fees

In civil cases, fees are established at the initial contact, and a retainer fee is requested and obtained with the materials sent by the plaintiff's attorney prior to the examination. Defense attorneys representing insurance companies may or may not be in a position to offer retainer fees. Psychiatrists should ascertain that fact at the outset.

Some psychiatrists prefer examining plaintiffs without first looking at records in order to preserve "neutrality." They do not wish to be influenced by the findings of others or by previous records before examination. That appears to be a difficulty in forensic cases, because one really needs to know the issues before exploring in a blind manner. The examination questions need to be focused on issues relevant to the particular case. Therefore, all available data should be requested at the outset. During the examination, one may be alerted to records that had not been previously obtained, and should insist on receiving them before proceeding further.

It is usually important for the psychiatrist to discuss the findings of the examination with the attorney before preparing a report. The attorney should be given the expert's preliminary opinions and should be told what additional information is required before a report can be written. The attorney may advise the psychiatrist not to prepare a report, e.g., if the attorney does not consider the psychiatric opinions helpful. In most jurisdictions, if the plaintiff's attorney is not going to utilize the psychiatrist at trial, the psychiatrist may not be identified as an expert and no report need be required or turned over to the defense attorney. However, all defense examinations are known to the plaintiff's attorney, and reports, helpful or not, are usually required.

Preparation of the report

It is important to include all relevant information in the expert psychiatric report. An attorney occasionally may ask, in a civil case, whether certain information about prior accidents or injuries may be left out of a report in order not to "prejudice" the case. This is not a good idea because a total evaluation includes all relevant information, especially prior injuries. If the attorney insists on having a report without this information, it is best not to prepare a report.

However, in criminal cases there are rules of evidence that may preclude placing certain information in the final report. For example, history of previous criminal behavior may be left out if the report is going to be shown to the jury. Juries are not to be told of prior criminal activity, as that could prejudice the jury in the particular case. Thus, there are rules that one must follow, and one should not be constrained about removing information that may be harmful to the individual examined, if the court agrees and orders that the information be deleted.

May a report, once prepared, ever be modified or changed at the request of the attorney? This is a very sensitive issue that affects all forensic psychiatrists. If, upon request, the forensic psychiatrist deems the changes to be necessary, and if the changes would not adversely affect the opinion, the psychiatrist may make the changes and send a revised report to the attorney. The psychiatrist should clearly indicate that this is a revised version of a previous report. Occasionally, the attorney would not wish to have the report so marked as revised, but would rather present only one report that includes the revisions and discard the original report. In those cases, it is appropriate to label the original report a preliminary report.

It is usual for good attorneys, on cross-examination, to ask if the expert has ever prepared an earlier version of the report submitted. In answering such a question, the psychiatrist must be truthful and explain why the changes were made. If the psychiatrist does not have a copy of the original preliminary report, there may be some implication made on cross-examination that the psychiatrist had something to hide by discarding the earlier version. Thus, it is important to retain early reports to indicate what changes were made and for what reasons.

It is essential that the expert does not lie at the request of the attorney and indicate that there was no preliminary report when, in fact, there was. There may have been several preliminary reports that had been revised several times. That fact, if questioned, should be made known to the jury as a matter reflecting credibility, truthfulness, and integrity. In addition, to lie in court about an earlier version of the report would be perjury—a felony punishable by fine or prison. The best way to avoid such a problem in court is to prepare only one report after full consultation with the attorney about the material to be included and the structure of the report.

In most jurisdictions, draft reports are currently not discoverable.

Examination of the plaintiff

The psychiatrist working for the plaintiff's attorney may see the plaintiff several times before rendering an opinion or writing a report. When working for the defense attorney, the psychiatrist may have only one shot at the examination and should make the most of it. Thus, it is suggested that ample time be allowed for such an examination.

Occasionally, the plaintiff's attorney will wish to be present during the examination by a defense-appointed psychiatrist. This has become a matter of controversy and debate among psychiatrists and forensic psychiatrists. Many psychiatrists without forensic experience do not enjoy the prospect of conducting such an examination in the presence of third parties. They argue that others present in the

examining room dilute the traditional one-on-one relationship and the examination is conducted in less than ideal circumstances. Some psychiatrists refuse to examine an individual in the presence of others. However, many forensic psychiatrists understand the needs of plaintiffs to have representation during every stage of their proceedings. The examination by a defense psychiatrist may be a traumatic experience for the plaintiff, who may be comforted by having an ally in the room (Sadoff 2011). That person may be the attorney, a paralegal, or a representative of the plaintiff's law firm. The examining psychiatrist may require that person to sit behind the examinee and not give cues or signals during the examination.

Interruptions of the examination should not be tolerated unless the attorney representing the plaintiff feels that the question asked is intrusive, inappropriate, or irrelevant. There usually are no serious problems having the plaintiff's attorney present, taking notes, listening, and observing. However, there are times when plaintiffs' attorneys wish to record the examination session. The forensic psychiatrist may agree or refuse to have the session either audio or video recorded unless the examiner is able to obtain a copy of the recording and/or a copy of the transcript of the audio recording. Some forensic psychiatrists video record every examination they conduct. Of course, the recording of the interview itself can introduce distortions to the database (Falls et al. 2014).

Preparation for trial

As noted previously for criminal cases, pretrial preparation is absolutely necessary in civil cases and should occur prior to the psychiatrist entering the courtroom. The psychiatrist should know precisely what questions are to be asked on direct, and should be able to anticipate cross-examination questions. The psychiatrist should then discuss his or her responses to such anticipated questions with the attorney, so that the attorney is also prepared.

On occasion, there will be information that has not been provided to the expert. This may be a letter, a report, or even a deposition. In some cases, the expert has not had the time or availability to interview various people involved in the case. Very often, when working for the defense in a criminal case, the expert does not interview the arresting officers or members of the victim's family. That fact may be brought to light under good cross-examination to show the jury how "incomplete" the psychiatrist's investigation has been. When asked if individuals had been interviewed, the best response is a factual "no." If given the opportunity, one may explain why such examinations were not conducted, as due to limitations of time, resources, or availability, or even the unwillingness on the part of the other witnesses to be interviewed.

When the cross-examination involves showing the psychiatrist a document that was never reviewed, it is prudent for the expert, when surprised in such a manner on the witness stand, not to offer the opinion, "Yes, it automatically changes my opinion," but to indicate that the document reveals new information that has not previously been reviewed. The psychiatrist may wish to take some time to review that document and its impact on the opinion before reaching a conclusion to be offered to the jury.

ESTABLISHING A PRACTICE OF FORENSIC PSYCHIATRY

It is impossible to address all the practical points needed to avoid problems in the practice of forensic psychiatry. Salient practical advice that confronts forensic psychiatrists on a daily basis is offered herein in condensed form (Dattilio and Sadoff 2007). However, prudent forensic psychiatrists will have supplemented their education with a fellowship in forensic psychiatry before embarking on a career in this increasingly complex subspecialty of psychiatry. Since 2001 psychiatrists have to complete a forensic psychiatry fellowship accredited by the Accreditation Council for Graduate Medical Education (ACGME) before they are allowed to take the examination for board certification in forensic psychiatry. A current list of accredited Forensic Psychiatry Fellowship Programs can be found on the American Academy of Psychiatry and the Law (AAPL) website (http://aapl.org). One does not need board certification in forensic psychiatry to practice as a forensic psychiatrist, but it does add to the credibility of the individual as an expert witness.

Psychiatrists who do not wish to take a fellowship in forensic psychiatry should in the alternative enlist a practicing forensic psychiatrist as a mentor or consult with a leader in the field. Certainly, aspiring forensic psychiatrists should read the literature and be familiar with the leading cases that affect the functions of the forensic psychiatrist. It is not always easy to get started in the field in an area saturated with competent forensic psychiatrists. However, aspiring forensic experts can give lectures to lawyers' groups and can work in clinics and other forensically oriented facilities where their skills will become known to attorneys who may wish to avail themselves of such services. Writing articles for attorneys is also a means by which to become identified as a prospective expert.

It is not recommended to advertise one's wares or skills in legal journals or daily newspapers. Commercial expert witness groups that charge fees and provide experts to attorneys around the country should also be avoided. On cross-examination, one can easily be exposed as belonging to such a "factory" or "mill," as they are called. However, there are legitimate professional advisory groups that do provide forensic services to attorneys. One may affiliate with such a group and be available for consultation when needed. It would be unwise, however, to become involved in a group where membership fees are paid in order to have one's name on a list of potential experts.

It is also wise not to offer one's skills by soliciting to consult on a particular case. It is better to wait for the attorney to call the expert. However, it is proper for psychiatrists to let their colleagues know that they are interested in taking

cases with legal ramifications. Working on the medical–legal committee of one's local medical society is another means of exposure for subsequent consultations. By and large, the best means of identifying oneself as a forensic expert is to express an interest, take a fellowship in an accredited program, and work under the tutelage of competent and experienced forensic experts.

There have been a number of changes in the field of forensic psychiatry in the past decade. The rise of managed care has stimulated further interest in forensic psychiatry because it tends to be "managed care free." The membership of the AAPL that began in 1969 with eight original members had over 1900 members as of January 2015. Most psychiatrists practicing forensic psychiatry are not full time in the field, but also maintain a private treatment practice. It is important for practicing psychiatrists to be aware of potential conflicts of interest when their patient becomes involved in a legal matter. In most cases, it is unwise and a potential conflict for a treating psychiatrist to act also as the expert witness for his or her patient. Claims of bias to help one's patient will be brought, as well as the difficulty of being able to strive to reach an objective opinion, as required by the AAPL ethics guidelines, that is essential in the ethics of forensic psychiatry. Furthermore, testifying for a patient who does not do well in court may reflect on the subsequent treatment of the patient and the therapeutic alliance necessary for successful therapy (Strasburger et al. 1997).

Another potential problem for practicing psychiatrists is scheduling. The demands of forensic psychiatry may preclude a psychiatrist from regular sessions with particular patients. The judge may require the psychiatrist to be in court during a regularly scheduled patient time. That can be quite disruptive to patients who depend upon regularity of sessions because of their own schedule.

There are some cases that should be avoided by the private practicing forensic psychiatrist. These include evaluating police officers or security guards for clearance to carry a gun. This is a no-win situation. If the psychiatrist clears a guard or a police officer to carry a gun and that person later misuses the weapon, the psychiatrist will be blamed for incomplete assessment and making a recommendation that was improper. If, however, the psychiatrist determines the guard or the officer to be at a special risk for carrying a weapon, such persons may sue the psychiatrist for depriving them of making a livelihood (Sadoff 1998).

Similarly, examining sex offenders to determine whether they are "dangerous" may also have peril for the forensic psychiatrist (Sadoff 1998).

Ethical questions may arise when a forensic psychiatrist is asked to evaluate a prisoner on death row who has become acutely mentally ill. What is the role of the psychiatrist in recommending treatment or providing treatment for inmates in order to alleviate their mental condition so that they can then be put to death? The American Medical Association has taken the position that it is unethical to treat inmates to make them competent to be executed. However, it is ethical to treat an inmate incompetent to be executed to relieve suffering or maintain prison security, even if that is likely to make the inmate competent to be executed (American Medical Association 2000).

Finally, due to the recent proliferation of psychiatrists carrying out forensic work, the American Psychiatric Association and the AAPL have developed peer review committees to assess and evaluate the appropriateness of forensic assessments and testimony.

SUMMARY

The practice of forensic psychiatry is rewarding and exciting, but may also be frustrating and very difficult for the uninitiated. It is strongly recommended that anyone who is seriously interested in practicing forensic psychiatry take a fellowship training year or work with a competent, respected forensic psychiatrist as a mentor. Read the literature and follow the rules to avoid obvious pitfalls. Never work on a forensic case unless an attorney is involved. Occasionally, plaintiffs or clients will call, indicating that they are going *pro se* without an attorney. It is much more difficult to work with individuals who do not have the guidance of an attorney in this very complicated area. The more one knows, the better protected one is. There is much to know in a substantive manner, but one also needs to know the practical issues that affect all forensic psychiatrists.

ACKNOWLEDGMENTS

I am indebted to Julie B. Sadoff, Esquire, for her careful reading of the manuscript and her helpful suggestions with respect to legal issues.

Education and training in forensic psychiatry

RUSTY REEVES, RICHARD ROSNER, JOHN GUNN, DAVID REISS, AND DOMINIQUE BOURGET

INTRODUCTION

Since the early 1980s, education and certification in forensic psychiatry have grown more uniform and systematic in the United States, the United Kingdom, and Canada. Although many forensic psychiatrists continue to practice without formal training in the subspecialty, formal training and certification in forensic psychiatry is the preferred route into forensic psychiatry. In this chapter, the authors, who are educators and practitioners, describe the educational programs and methods of certification in their respective countries. A reader curious about education and certification in any other country should contact its national psychiatric association or national association for psychiatry and the law.

UNITED STATES

Education

The Accreditation Council for Graduate Medical Education (ACGME) is the accrediting body for all graduate medical education programs in the United States. In 1997, the ACGME began to accredit fellowships in forensic psychiatry. As of the 2014–2015 academic year, the ACGME had approved 40 programs with a total of 66 trainee positions as meeting its criteria for accreditation in forensic psychiatry (ACGME 2014a).

In the more than 10 years since the previous version of this chapter was written (Reeves and Rosner 2003, 52–55), the basic requirements for training in forensic psychiatry remain unchanged (ACGME 2013). The ACGME still requires that the training period in forensic psychiatry be 12 months, and that training occur after completion of a psychiatry residency program accredited by the ACGME. The program must be administratively attached to and sponsored by a residency program in psychiatry that is accredited by the ACGME. An assignment to a participating institution must include a program letter of agreement. Major changes to the program require approval by the sponsoring institution's Graduate Medical Education Committee, and then by the ACGME's Psychiatric Residency Review Committee (RRC).

The program director organizes and manages the activities of the educational program in all institutions that participate in the program. The program director and physician faculty must be certified by the American Board of Psychiatry and Neurology (ABPN) in the specialty of forensic psychiatry, or have qualifications in forensic psychiatry that are acceptable to the RRC.

Fellows' educational experiences must include at least 6 months of evaluating and managing patients in corrections, working with professionals in both forensic and community settings, reviewing written records, preparing written reports, providing testimony, and providing consultations to general psychiatric services on issues related to the legal regulation of psychiatric practice. The didactic curriculum must include all topics for which fellows must demonstrate competence in knowledge, such as the legal system, civil law, criminal law, and relevance of legal documents.

The ACGME requires that the program integrate into the curriculum, and the fellows demonstrate, six ACGME-required competencies: patient care and procedural skills, medical knowledge, practice-based learning and improvement, interpersonal skills, professionalism, and systems-based practice.

New for all medical specialties, and effective July 2015 for forensic psychiatry, the ACGME further requires each resident achieve "milestones" within the above-mentioned six competencies. According to the ACGME, a milestone is a "significant point in development." In forensic psychiatry, for example, under the "Patient Care" competency, a forensic fellow is expected to achieve the milestone of providing psychiatric care in a forensic setting that "consistently manages security concerns, dual agency, and the potential for conflicts with therapeutic efforts" (ACGME 2014b). Milestones are demonstrated progressively by residents and fellows from the beginning of their education to

the unsupervised practice of their specialties. In forensic psychiatry, these milestones are assessed on a semi-annual basis. The ACGME requires reporting of achievement of milestones beginning in November or December 2015. The above are but a few of the ACGME requirements for education in forensic psychiatry. A summative evaluation for each fellow is completed at the end of the program to ensure fellows are able to practice independently. The entire list of requirements can be found on the ACGME's website (http://www.acgme.org).

The Association of Directors of Forensic Psychiatry Fellowships (ADFPF), a council of the American Academy of Psychiatry and the Law (AAPL), works to ensure quality education in forensic psychiatry along with providing a venue for forensic program directors to exchange ideas and remain up-to-date with developments relevant to training in forensic psychiatry. The ADFPF assisted in the creation of the above-mentioned milestones required by the ACGME. The ADFPF meets twice a year, at the annual AAPL meeting and at the annual American Psychiatric Association (APA) meeting.

Certification

The ABPN is the organization responsible for offering certification examinations in psychiatry and neurology. The ABPN is a member of the American Board of Medical Specialties (ABMS), an organization of 24 approved medical specialty boards. The ABPN in 1994 began to offer a certification examination in forensic psychiatry.

In order to take the ABPN forensic exam, an applicant must first be certified by the ABPN in psychiatry (ABPN 2014a). Applicants are required to submit documentation of successful completion of 1 year of ACGME-approved residency training in forensic psychiatry. The ABPN's initial certification examination in the subspecialty of forensic psychiatry is a 200-item, multiple-choice, 4-hour computerized test that assesses candidates' knowledge in legal regulation of psychiatry, civil law, criminal law, death penalty, legal systems and basic law, children and families, special diagnostic and treatment issues, special procedures in forensic psychiatry, special consultations and investigations, risk assessment, and forensic psychiatry practice issues (ABPN 2014a).

ABPN certificates for forensic psychiatrists are valid for 10 years; thereafter, successful completion of maintenance of certification (i.e., recertification) examinations is required to sustain ABPN forensic certification. The recertification examination is a 150-item, multiple-choice, 3-hour computerized test. In a welcome development for 2015, the ABPN offers combined maintenance of certification examinations in specialty and/or subspecialty examinations. The combined maintenance of certification examination in psychiatry and forensic psychiatry is a 5-hour and 15-minute examination with 100 questions in psychiatry, and 100 questions in forensic psychiatry. It also is possible to take a combined examination in two subspecialties.

Since 2007, admission to the recertification examination has required prerequisites. The process of completion of these prerequisites is called Maintenance of Certification (MOC) (ABPN 2014b). The ABPN has established MOC to encourage lifelong professional learning among its certified psychiatrists. MOC includes accumulation of sufficient Continuing Medical Education credits, and completion of self-assessment (SA), and performance-in-practice (PIP) activities. While understanding the necessary MOC activities may be confusing, completion of the activities is not daunting. Any CME, SA, or PIP activities completed apply to all specialties/subspecialties in which a physician is certified. Thus, a psychiatrist does not have to double the number of MOC activities in order to be certified in both psychiatry and forensic psychiatry. As of September 2, 2014, the ABPN from 1994 to 2013 had issued 2125 certificates in forensic psychiatry, of which 1455 were current (Vollmer, ABPN, personal communication, 2014). The above represents a summary of ABPN requirements with a full list of requirements available from the ABPN (http://www.abpn.com).

UNITED KINGDOM

International standards

Within the European Union all medical training is not yet harmonized between member countries, resulting in professional frustration about this barrier to potential movement between countries in some specialties, including forensic psychiatry. Only the United Kingdom, Germany, Sweden, and Finland have specialized training in forensic psychiatry at present, but this pattern is likely to spread.

The United Kingdom is in a strong position to control standards in forensic psychiatry because its state monopoly National Health Service, together with the professional monopoly of the Royal College of Psychiatrists, can control appointments in the specialty. As forensic psychiatry has until recently been a shortage specialty at the consultant level, there continues to be some slippage, and de facto general psychiatrists take on a limited amount of forensic work.

Education

Numerous recent changes have taken place to the structure and regulation of U.K. medical training, some changes in accordance with European Union medical directives. The Postgraduate Medical Education and Training Board, created April 2003, was combined with the General Medical Council (GMC) on April 1, 2010. With these changes, the GMC now regulates all postgraduate medical training, setting appropriate requirements. In England, Health Education England, established June 2012, has 13 Local Education and Training Boards (LETBs, working from April 1, 2013) that are area-based committees responsible for National Health Service (NHS) staff education and training. Local deans' offices, which previously had responsibility for NHS medical staff training in England, continue

to perform this function in Northern Ireland, Scotland, and Wales. The "Shape of Training" report (Greenaway 2013) has recommended changes to postgraduate education and training that should, if implemented, still produce specialists but result in more generalist doctors working in broad specialties. These changes will not be finally determined until subsequent to the 2015 general election, and the implications for forensic psychiatry are not yet clear.

The United Kingdom's Royal College of Psychiatrists (RCPsych) runs a "Membership" examination (MRCPsych) for psychiatrists who have completed basic specialist training (equivalent to general psychiatry residency training in the United States). A psychiatrist must pass papers A and B as well as the Clinical Assessment of Skills and Competency (CASC) of this examination before being allowed to enter higher specialist training in one of the U.K.-recognized psychiatric subspecialties (see below). Paper B and the CASC contain questions on forensic psychiatry for all trainees to answer. Passing the MRCPsych is similar to passing the ABPN certification examination in general psychiatry in the United States, but it is more than just a qualification and gives immediate access to professional and educational activities within the Royal College of Psychiatrists.

A placement (rotation in the United States) in forensic psychiatry, usually of 6 months' duration, is a noncompulsory option in basic specialist training. These have to meet RCPsych specified standards, including a job description, timetable, and satisfactory clinical supervision, as well as having specific training experiences including consultations at prisons, hospitals, secure units, remand centers, and other establishments. Trainees are encouraged to write shadow reports for discussion with their consultants, as well as to be instructed in the principles of forensic psychiatry and medico-legal work.

After the completion of basic specialist training, and the passing of the MRCPsych, a psychiatrist who wishes to specialize in forensic psychiatry may enter higher specialist training. Forensic psychiatry is one of six areas of higher specialist training, with the others being general (adult) psychiatry, old age psychiatry, child and adolescent psychiatry, psychiatry of learning disability, and psychotherapy. Entry to this training is through U.K.-wide competitive interview.

For all medical postgraduate training schemes, the GMC approves curricula and assessment systems, although these are designed by the royal colleges. To complete forensic psychiatry higher training, trainees must follow and achieve a detailed competency-based curriculum, which details the intended learning outcomes for advanced specialist training. The RCPsych writes the training curricula through Faculty Education and Curriculum Committees which report to an overarching Curriculum Committee. The GMC has responsibility for quality assurance to ensure that regulatory requirements are met: it inspects training programs, publishes its findings, reviews reports from the training organizers as well as the medical royal colleges, and conducts annual national surveys of trainees and trainers.

The forensic trainee must learn how to manage offender patients in all relevant settings, including prisons, the community, specialist hostels, and hospitals, especially secure hospitals. Trainees move through a variety of different services to satisfactorily develop these competencies. Most trainees undertake some additional private work, and medico-legal experience may be acquired in all settings. Every detained patient in the United Kingdom, as well as those on Community Treatment Orders, has a periodic right to apply to a Mental Health Tribunal for review of the detention/order, which is exercised by the majority. There is, therefore, an emphasis on medico-legal work for these hearings. Criminal court work is a relatively small proportion of a forensic psychiatrist's workload, involving mainly some sentencing decisions.

Certification

Completion of forensic psychiatry training usually takes 3 years and results in the award of a Certificate of Completion of Training (CCT), which is essential for appointment to an NHS consultant post. A surprisingly small proportion of the knowledge and skills that are required to undertake the role of a British consultant forensic psychiatrist is mandatory, but the emphasis is on clinical work. There is no exit examination in any of the higher psychiatric specialties. Rather, every trainee in forensic psychiatry is annually evaluated by the scheme organizer and the LETB or dean's office, to determine whether the trainee is allowed to progress to the next year and, ultimately, to be awarded a CCT.

CANADA

Education

Historically, Canadian forensic psychiatry fellowship programs were accredited by the U.S. Accreditation Council on Fellowships in Forensic Psychiatry (ACFFP). In 1997, when the ACGME replaced the ACFFP, Canadian postgraduate medical programs were no longer able to receive accreditation (Reeves et al. 2007).

These developments did not deter the evolution and practice of forensic psychiatry in Canada. Even though forensic psychiatry was not formally accredited or recognized as distinct from the practice of general psychiatry, forensic psychiatry developed with a strong community of psychiatrists devoted to their practice. In 1996, the Education Committee of the Canadian Academy of Psychiatry and the Law (CAPL) developed a standardized Forensic Psychiatry Training Curriculum. A revised curriculum was formally endorsed by CAPL in 2004 (O'Shaughnessy 2004).

On September 29, 2009, the Council of the Royal College of Physicians and Surgeons of Canada (RCPSC) recognized forensic psychiatry as a subspecialty in psychiatry (Bourget and Chaimowitz 2010, 158–162). The RCPSC is the professional body that develops specialty-training requirements and accredits residency programs in Canada.

Prior to entering subspecialty training, residents must have completed 5 years of residency in general psychiatry, in accordance with the General Objectives of Training and Specialty Training Requirements in Psychiatry, and successfully completed the RCPSC examination in psychiatry or equivalent (Royal College of Physicians and Surgeons of Canada 2003). This stems from the principle that forensic psychiatry arises from and requires a thorough grounding in general psychiatry.

There are currently five accredited forensic psychiatry residency training programs in Canada, and several others have initiated the process toward accreditation. Each program is headed by a program director (PD), responsible for the overall conduct of the residency program. Moving toward accreditation has brought about significant changes in the way forensic psychiatry is now taught across the country. Standardization of training is one of the main results. The RCPSC has established "Minimum Training Requirements," which include a period of no less than 12 months of approved residency training commencing after successful completion of specialty training in psychiatry. The year is divided into 13 four-week blocks that include 6–9 blocks of core training.

Core training involves clinical exposure and typically includes assessments for fitness to stand trial and criminal responsibility (and relevant mitigating factors), and risk assessments. This takes place in various settings, such as inpatient and outpatient units, mental health courts, or detention centers. Core training is also concerned with provision of treatment to mentally ill offenders. In addition to core training, the resident must complete four to seven blocks of selective training that include at least two content areas drawn from the following: child and adolescent forensic psychiatry, civil psychiatry, correctional psychiatry, sexual behaviors, risk assessments, and forensic research. Mandatory and selective training may be undertaken as discrete rotations or longitudinal experiences, which is often felt to be ideal, given that cases often take some time before reaching the next stage of resolution.

Upon acceptance into the specialty program, trainees are assigned a supervisor who acts as an advisor to the trainee and ensures that opportunities to meet the optimal training requirements are made available to the trainee. Throughout their training, trainees are evaluated through evaluation reports, review of their written reports, and constructive critiques of testimony offered during the course of training. At the end of training, the PD submits a final report to the RCPSC, with regard to each trainee having completed residency training.

Now that the RCPSC recognizes forensic psychiatry as a distinct subspecialty of psychiatry, training programs are eager to deliver the best quality of teaching and to prepare the next generation of forensic psychiatrists. One of the biggest challenges thus far has been the securing of funding for post-general residency positions. As forensic psychiatry is a new subspecialty, there was no tradition to fund these programs. Nevertheless, the first trainees began accredited training in July 2012.

Certification

The RCPSC is responsible for certification examinations for Canadian physicians in various specialties and subspecialties. After successful completion of the forensic training, candidates submit their applications to the RCPSC to determine their eligibility to take the certification examination. The RCPSC has granted a temporary period to allow candidates without a formal training year and already engaged in the practice of forensic psychiatry, via the Practice Eligibility Route, to request an assessment of their credentials for examination eligibility.

The certification examination format currently consists of a 3-hour-long written examination of approximately 40 short answer development questions. The first cohort took the examination on September 26, 2013. This cohort included a large number of psychiatrists already practicing in the subspecialty.

The certification delivered by the RCPSC attests to the completion of specialty training requirements in an accredited program. This holds true for all Canadian provinces except Quebec. The medical profession in Canada is granted a significant degree of authority by provincial law, and the province of Quebec has its own regulating body. While most provinces recognized the competence of the RCPSC for certification, Quebec took years to harmonize its own examination with that of the RCPSC. However, subspecialties in psychiatry have not yet been recognized in Quebec, so RCPSC certification cannot be used by forensic psychiatrists in Quebec in their title at this time.

SUMMARY

The United States, the United Kingdom, and Canada have standardized training in forensic psychiatry through accreditation by authoritative professional organizations. A forensic psychiatry fellowship as offered in these countries provides an intense and systematic education in forensic psychiatry, with exposure to the field's diversity, and close supervision from experienced and certified practitioners. At the end of training, the physician has been certified by his or her supervisors to independently practice forensic psychiatry. Board certification in forensic psychiatry in the United States and Canada offers additional assurance that a physician meets a level of competence in the field.

Forensic psychiatric ethics

ROBERT WEINSTOCK, WILLIAM CONNOR DARBY, PHILIP J. CANDILIS, GREGORY B. LEONG, AND JENNIFER L. PIEL

INTRODUCTION

Forensic psychiatry operates at the interface of two disparate disciplines—law and psychiatry—with differing objectives, philosophies, values, approaches, and methods. Psychiatry, a branch of medicine, endeavors to improve mental health and to help patients. Historically, Hippocratic physicians saw their duties primarily to individual patients. However, the responsibilities of physicians both ethically and legally have been extended in modern times to society as a whole. Medical ethics incorporates deontological (adherence to duties), utilitarian or consequentialist, and virtue ethics. In contrast, the law operates with justice, retribution, containment, and deterrence as its goals. Dilemmas can occur when ethical and legal considerations conflict and some ethical values may be compromised.

Although ethical conflicts do not occur in most ordinary situations at the interface of law and psychiatry, conflicts between principles, roles, duties, rules, systems, and stakeholders have the potential to create dilemmas in forensic psychiatry. In these relatively uncommon situations, there may be no clear, unequivocally relevant rule or ethics guideline to follow that does not impinge on some other competing consideration (Childress 1997). Moreover, no universally dominant consideration exists as to necessarily outweigh all others in every situation. Thus, the context in these special circumstances will be essential in determining the most ethical action.

Professional ethics guidelines in forensic psychiatry provide sufficient assistance in most contexts to help practitioners address and resolve what to do. But no set of ethical guidelines can address every possible contingency. Although ethical guidelines are extremely helpful, there often is not one clear answer and several can be acceptable when ethics dilemmas arise. As a result, forensic psychiatrists must be able to perform their own analyses in ethically complex cases.

ETHICAL FOUNDATIONS AND ALAN STONE'S CRITIQUE

Stone (1984), in a paper originally presented at the American Academy of Psychiatry and the Law (AAPL), stimulated much concern and debate by positing that the ethical requirements and boundaries of a healing profession become unclear once psychiatrists leave the therapeutic realm. Four problem areas can be distilled from Stone:

1. The basic boundary problem of whether psychiatry has anything to offer the law
2. The potential for psychiatrists to try to help a patient by twisting rules of justice and fairness
3. The potential for the psychiatrist to deceive a patient in order to serve justice and fairness
4. The power of the adversarial legal system to both seduce and abuse psychiatrists in ways that demean the profession

Stone cautioned that physicians lose their ethical boundaries when they give other factors such as justice, advancement of science, or political causes greater weight than helping patients or doing no harm. In his opinion, psychiatrists cannot simply adjust to the adversarial system and still remain true to their calling as physicians.

Stone also stated that juries do not clearly understand the partisan role of forensic psychiatrists, or that when forensic psychiatrists testify they "should be understood as having attempted to present the best case possible" (Stone 1984) for the retaining party. Stone argues that until there is candor, it will not be possible to "sweep the ethical problems of psychiatry under the rug of intelligible adversarial ethics." However, these problems are not unique to forensic psychiatry—they can arise for all expert witnesses who testify under an adversarial system. If changes were to be made, they would necessarily involve the entire adversarial

process and its use of expert witnesses, because most issues do not pertain solely to forensic psychiatry.

Stone identifies another potential pitfall, the problem of reconciling deterministic psychiatric theories with a legal system based on free will. For instance, Moore (1984) contends that mind–brain confusion in American forensic psychiatry goes back at least to Isaac Ray, who thought that if mental disease is physical, the power to choose is extinguished and the actor is *ipso facto* not responsible. According to Moore, the law—in contrast to science—uses the language of action and reason with possible physical causes of mental illness therefore irrelevant to whether the law should excuse a behavior.

In a 2014 study, Appelbaum and Scurich (2014) explored how the introduction of behavioral genetic evidence could affect the perception of criminal responsibility. The data from their representative U.S. sample suggest that a genetic predisposition to violence did not alter decisions regarding degree of criminal responsibility or mitigate sentencing. These findings differed from a study of state criminal court judges whose hypothetical sentences were significantly reduced when there was evidence attributing a defendant's psychopathy to genetic causes (Aspinwall et al. 2012).

Such problems of role confusion exist even in the realm of treatment psychiatry and are not exclusive to forensic psychiatry. Society has progressively thrust conflicting responsibilities on treatment psychiatrists. For example, in child or elder abuse, other requirements and concerns may take precedence over patient welfare (Weinstock et al. 1991), especially in those jurisdictions in which reporting can lead to prosecution of a patient (*People v. Stritzinger*, 1983). In California, psychiatrists can be placed in a position to testify against their patients. Therefore, the ethical boundaries of treating as well as forensic psychiatrists sometimes may be obscured and not clearly demarcated. Thus, although forensic psychiatry deals with unique considerations inherent to functioning at the interface of law and psychiatry, the need to balance conflicting factors is common to most psychiatric roles.

ETHICAL PRINCIPLES RELEVANT TO FORENSIC PSYCHIATRY

Appelbaum (1990) wrote, "Psychiatrists operate outside the medical framework when they enter the forensic realm, and the ethical principles by which their behavior is justified are simply not the same." He contends that the principles of beneficence and nonmaleficence lose their primacy to the principles of truth in the forensic setting. Although ethical conflicts sometimes can arise, Appelbaum (1984) contends that forensic psychiatrists should present both the subjective and objective truth.

AAPL in its ethics guidelines (AAPL ethics guideline 2005) has similar concerns in requiring honesty and striving for objectivity. Psychiatrists should not stop with a convenient subjective truth as soon as they collect some evidence that substantiates it even if they are persuaded by that. They should go beyond their initial subjective, honest belief and strive to reach an objective truth by collecting as much evidence as they can, including evidence that may contradict their initial impression. Objective truth requires making evident any limitations on their conclusions. In order to strive for the most objective opinion, efforts should be made to become as familiar with the relevant literature as possible. In addition to the current AAPL ethics guideline necessitating an effort to strive for objectivity, the AAPL guidelines also require honesty. But, an honest opinion with little to substantiate it is insufficient. A careful search for and review of evidence could result in the subjective truth approaching the objective truth.

Appelbaum (1997) considers respect for persons as the second moral rule guiding forensic psychiatric ethics after that of truth-telling. He alerts forensic psychiatrists to a major risk that "subjects of forensic evaluations will assume that an evaluating psychiatrist is playing a therapeutic role and, therefore, that the usual ethics of the clinical setting apply." Evaluees may believe that, as physicians, forensic psychiatrists are there to help or at the very least do no harm to them, and may subsequently think it is safe to speak freely. According to Appelbaum, while "allowing subjects to hold such beliefs might be an effective means of gathering information, it is inherently deceptive and exploitative, and fails to respect subjects as persons." That ethical concern applies regardless of what the law permits.

Additionally, according to Appelbaum (1997), forensic psychiatrists "cannot avoid the obligation of determining whether the actions they are being asked to perform in fact promote justice." For example, assisting in abusive interrogation or torture of prisoners would fail that test. Overall, the primary duty of forensic psychiatrists according to Appelbaum is to assist the legal system to promote justice. But realistically there are limits to which forensic psychiatrists are allowed to impose their views of justice on the legal system. Also, forensic psychiatrists like all citizens have duties to behave nonmaleficently, even though some maleficence may be a consequence of some forensic roles.

Appelbaum states that violating moral rules is an inevitable consequence of the complexity of life, and resolving such conflicts "requires balancing, among other morally relevant factors, the nature of each imperative, the benefits and harms likely to flow from its violation, and the alternative means of achieving the desired end." He states that although moral ideals are desirable rather than required, morals rules are required of individuals. Professional ethics can transform a moral ideal into a moral rule. An example is the requirement of physicians to relieve pain, which is only an ideal for the general public. According to Appelbaum, the moral ideals that should be converted into moral rules are those values that society wants the profession to promote. Society gives professions certain privileges in exchange for certain duties and the expectation for self-regulation. Differences between the ethics of differing professions should reflect society's expectation of the profession.

Appelbaum (1997) supports a principled approach and recognizes a need to balance conflicting duties when complex ethical problems arise. He cautions, "if forensic psychiatrists persuade themselves that they maintain a residual duty—of a professional nature—to benefit and not to harm evaluees, they are likely to communicate that to their subjects." There is a risk of engendering inappropriate trust when the forensic psychiatrist is on the side opposite the person being evaluated. An evaluee could be misled into thinking the forensic evaluation is a quasi-therapeutic encounter. In the process of mutual deception, the subject could be betrayed and potentially seriously harmed.

In Appelbaum's view, that is an advantage of deriving the ethics of forensic psychiatry from the pursuit of justice and not health, thereby sending a clear message regarding the distinction between the forensic and therapeutic roles. Some authors have proposed ways of analyzing this conflict (Rosner 1990; Candilis et al. 2007; Weinstock 2015).

The retention of traditional Hippocratic medical values as a consideration in forensic ethics is consistent with the findings from surveys of forensic psychiatrists. The highest-rated potential new ethical guideline in a survey of forensic psychiatrists was shown to be one that considered medical and psychiatric ethics as a factor when performing a forensic evaluation (Weinstock et al. 1991). A way to retain Hippocratic ethics while conceptualizing conflicting legal duties can be to see forensic psychiatrists as having multiple agency responsibilities similar to all other psychiatrists, especially those who consult to another system like a hospital, managed care organization, prison, school, or government agency with its own inherent rules and priorities. For all psychiatric roles, however, there is generally no simple, single duty that will always trump all other considerations.

In the judicial system there may already be an assumption that traditional medical ethics remains a consideration for all roles assumed by physicians, so eschewing medical ethics completely may in fact mislead judges and juries who may interpret the physician role more traditionally than the expert who rejects medical values.

Truth-telling can harm a patient even in the treatment setting, such as when the treater makes a diagnosis of antisocial personality or malingering. Thus, harm is not unique to forensic psychiatry. It is simply more frequent in some forensic roles. Fostering justice and truth-telling, however, have more primacy than patient welfare in most forensic settings. The opposite priority may be true in the treatment setting, or at minimum hold equal value.

Like Hundert (1990), Weinstock et al. (1990) have posited that traditional medical ethics should still play a role and be a factor in the process of balancing conflicting values. Weinstock (2015) develops the balancing method further.

Primacy, though, does not mean that the primary duty must always outweigh all secondary considerations. For instance, in unusual situations, the secondary duty can be especially serious, despite the presumptive primary duty, and even become determinative of the most ethical course of action. For example, in the treatment context, societal obligations outweigh the primary duty to patient welfare in instances like child and elder abuse. These are conditions that must be reported. Conversely, in the forensic context, performing pre-arraignment assessments and treating prisoners to restore competence to be executed are unethical because the responsibility to an individual trumps the primary role of assisting the legal system—recognized as an ethical guideline by both APA and AAPL. In cases like these, the serious damage that results from violating a secondary duty makes that duty predominant. Because of these conflicting values as well as misunderstandings about the adversarial process, forensic psychiatry has developed ethical guidelines specific to the situations they commonly encounter.

However, practitioners should not necessarily be sanctioned for behavior in which no clear guidelines exist and there is serious disagreement as to what is the most ethical action. AAPL's ethics committees can advise practitioners in difficult situations, and there may be legitimate differing opinions. Clinical ethics committees may be less helpful because they may view situations from a treatment perspective and balance the conflicting considerations differently. It remains for those practicing forensic psychiatry to analyze options from a variety of ethical perspectives and advance beyond any single, simplistic rule to the exclusion of all other considerations.

Griffith (1998, 2005) advanced the discussion of forensic ethics significantly by emphasizing the importance of cultural factors in forensic cases, and specifically highlighting dominant and nondominant group dynamics. Griffith argues that these cultural considerations often are given insufficient attention in ethics analyses. He requires a sensitivity to such issues as the frequent lack of respect for African Americans seeking justice, and for nondominant personal narratives as a whole, including dominance and political facets. Even if such sensitivity does not result in an assessment helpful to a defendant, nondominant cultural issues should be understood fully and any systemic unfairness acknowledged in the assessment. In Griffith's opinion, these are important reasons for psychiatrists from nondominant cultures, who are more likely to be sensitive to these issues, to remain in court.

Candilis et al. (2001, 2007) propose a robust view of the forensic role that integrates both the principled and narrative approaches. Central to their concept is professional integrity (or wholeness) tied to the community and its values, and reflects a community expectation of a broader more physician-based approach from its forensic experts. This approach recognizes the profession's own historical narrative and the internal set of duties, values, and ideals that are essential for professional identity. These values resist the vagaries of social and situational forces that may call for experts to put institutional values over those of vulnerable individuals.

This unified or integrative approach contrasts with views of professional ethics that see forensic work defined only as an agency of justice and the courts. Developing a professionalism

that protects vulnerable persons and values instead, allows for a broader view of professional integrity that acknowledges personal and traditional physician-based values.

Candilis et al. (2007) use Griffith's narrative ethics as a tool to augment the classic principlist approach espoused by Appelbaum and described and developed by Beauchamp and Childress (2013) in the clinical context. Principles, according to Candilis et al. (2001), still work at the theoretical level to create a framework for appropriate action, but require narrative to provide the detail found in the motives and intentions of individual experts and evaluees. Alone, principles in their opinion are inadequate to give guidance in complex forensic situations. Narrative operationalizes theory in a practical manner, describing the individual's unique path to the forensic encounter. It is a way to overcome Stone's silence on cultural narrative and Appelbaum's justice-laden approach. Consequently, forensic experts can take the evaluee's narrative into account, recognize their own personal biases in a case, and advocate for the profession's integrity when it comes under pressure from the judicial system. This "robust professionalism" in the views of Candilis et al. (2001) defends strongly against the practice of the "hired gun."

Ciccone and Clements (2001) fear ethics becoming arbitrary with narrative alone. They prefer an applied ethics approach entailing a probabilistic inductive theory of ethics and a systems epistemology-like context ethics. Norko (2005) considers compassion as relevant in forensic work and ethics.

Weinstock (2001) addresses the need to balance conflicting values, and conceptualizes consultation in forensic psychiatry as different in its specifics but not different conceptually from consultation to other systems such as managed care with values that differ from those of treatment. Even in research roles, a physician has duties to science but has ethical duties to remove a patient from a study if there is a serious risk of harm. Balancing conflicting considerations is a central element of dialectical principlism.

DIALECTICAL PRINCIPLISM

Dialectical principlism (Weinstock 2015) is a method of ethical analysis that provides a specific framework to enable balancing conflicting roles, duties, and principles. In dialectical principlism, "dialectical" describes the process by which apparently contradictory and competing considerations including principles can be synthesized into a coherent whole to help guide our action. Principles are interpreted in the broadest sense of the term. They may include, for example, the principle of fostering justice, answering the legal question honestly and as objectively as possible, the four principles of biomedical ethics—beneficence, nonmaleficence, autonomy, and justice (Beauchamp and Childress 2013)—meeting societal expectations, and following our personal values.

When faced with an ethical dilemma under the dialectical principlism model, it is essential to consider the specific context to determine which duties and principles are primary and which are secondary. After identifying the competing duties and principles, practitioners should then prioritize, weigh, and balance them. In the forensic role, the primary duty and relevant principles are to foster justice and answer the legal question honestly, truthfully, and as objectively as possible. Primary duties have special weight in the balancing process which ordinarily outweigh and thereby trump secondary duties. An unusually strong secondary duty in some contexts, however, could outweigh the presumptively primary one and become determinative.

For example, the secondary principle of nonmaleficence may outweigh the primary principle of fostering justice if asked by the prosecution to present only aggravating circumstances at the penalty phase of a capital case to help them obtain a death sentence. In this instance, the most ethical action may be to reject the prosecution's case at the penalty phase because the secondary duty to not do harm—death in this scenario—outweighs the primary duty to foster justice.

Conflicts among principles and duties are balanced in a manner that impinges as little as possible on each other (Childress 1997). Finally, the weighted principles are applied to the context in question. Those with little weight and importance in the situation may be deemed negligible and subsequently not be factored into the final decisional equation.

Intent is central in dialectical principlism. This approach is designed to help practitioners find the most ethical course of action rather than to penalize or get professionals into trouble. Intent is notoriously difficult for licensing or administrative bodies to determine but is more relevant for us as a tool of self-examination. It is consequently aspirational, because violations of intent cannot generally be enforced without mind reading.

The discomfort arising from challenging cases can be a signal of serious conflicting ethical considerations, and potentially a dilemma. Dialectical principlism accepts this unease as legitimate and appropriate and provides a framework to help experts determine the most ethical conclusion possible.

NO MEANINGFUL DISTINCTION BETWEEN ETHICS AND MORALS

Sometimes professional ethics have been distinguished from personal morals. However, such a distinction can be confusing because the terms "ethical" and "moral" generally have been used interchangeably. In the professional realm, "ethics" is the term usually used, while in religion, "moral" is the predominant term, though both are generally interchangeable. Sometimes problems are labelled "moral" when organizations choose not to address them but know that some members have strong ethical views on the issue in question (e.g., some death penalty roles). Sometimes legitimate differences of opinion exist about whether specific ethical concerns should apply to the entire profession. Diamond (personal communication, April 25, 1988) distinguished between organizational ethics and personal ethics. Personal ethics can be more stringent than organizational ethics, and can be held by individuals or groups

for personal reasons, but not shared by other practitioners. They may be strongly held but should not be forced on all professionals if there is a good ethical foundation for alternative approaches. They can nonetheless be powerful guides to clinical practice.

Dyer (1988) has distinguished between ethical guidelines that function in a punitive role and guidelines for good practice by the concerned psychiatrist—these are not enforceable but are aspirational and intended to be considered by psychiatrists trying to behave most ethically. For example, some of AAPL's ethical guidelines are inherently aspirational because they are impossible to enforce, such as the requirement to strive to be objective. Most of AAPL's ethical guidelines, however, are capable of being enforced should anybody wish to do so. They are aspirational only in the sense that AAPL does not enforce them. Though nobody else enforces them per se, they are relevant insofar as they elucidate guidelines of other organizations like the American Psychiatric Association (APA) who enforce many forensic issues that fall within their framework (Candilis et al. 2014). Although ethical guidelines are extremely helpful, there often is not one clear answer, and several actions may be acceptable when ethics dilemmas arise.

TRADITIONAL HIPPOCRATIC ETHICS

A guiding principle for medicine has been *primum non nocere*, or "first, do no harm." This principle is not part of the Hippocratic Oath, although the oath does enjoin the physician from using medicine to harm patients (or anyone) depending on the translation (Weinstock et al. 1990). There is evidence that *primum non nocere* was first introduced by Thomas Inman in 1860 (Sokol 2013). In the *Epidemics* authored by Hippocrates and his group, there is a similar statement: "As to diseases, make a habit of two things—to help, or at least to do no harm" (Hippocrates translated 1923), even though *primum non nocere* is nowhere in the Hippocratic Oath. This principle is also not specifically stated in the current American Medical Association (AMA) Principles of Medical Ethics. It does, however, still function "to establish physicians as a moral community (with) delineated obligations and responsibilities specific to the medical profession" (American Medical News 2000). The general public also perceives this as a dominant, fundamental ethical principle guiding medical practice. The Hippocratic Oath in modified forms still is recited in many medical school graduations. The Oath was modified to permit surgery, omit the need to swear by Apollo, eliminate the bans on charging for medical education, as well as eliminate the bans forbidding abortion, euthanasia, and interestingly, sex with patients (Hulkower 2009/2010); and it reiterates the primary duty to patients in a treatment role, though this is not the case in a forensic role.

Hippocratic ethics made a resurgence when medicine was introduced into medieval Europe, probably due to its similarities to the Catholic confessional, with its paternalism and secrecy. Current medical ethical codifications date back to Thomas Percival, who in the late eighteenth century wrote his *Medical Ethics* that presented a scheme for professional conduct with many features in common with the Hippocratic Oath. It became a model for ethical codes in the United States, even though it was not adopted as an approach in England. The United Kingdom has relied more on the honor of physicians, believing rules cannot cover all contingencies (Candilis et al. 2007). Similarly, in the legal area, the United Kingdom relies more on respect for physicians and does not have privilege laws. In 1847 a dispute among several schools of physicians in the United States led orthodox practitioners to found the AMA, which adopted a Code of Ethics patterned after Percival.

AMA PRINCIPLES OF MEDICAL ETHICS

In its introductions to the Principles, the AMA states:

> The medical profession has long subscribed to a body of ethical statements developed primarily for the benefit of the patient. As a member of this profession, a physician must recognize responsibility to patients first and foremost, as well as to society, to other health professionals, and to self. The following Principles adopted by the American Medical Association are not laws, but standards of conduct, which define the essentials of honorable behavior for the physician. (AMA 2001)

THE DEVELOPMENT OF AAPL ETHICS GUIDELINES

AAPL has developed an important set of ethics guidelines for the practice of forensic psychiatry. Although not enforced by AAPL, they can be used to flush out the meaning of guidelines that are part of the APA framework, because the APA guidelines are enforced through the APA local district branches, and many of the guidelines pertain to forensic psychiatric practice. In the commentary section of the ethics guidelines, it states:

> [T]he ethics committee may issue opinions on general or hypothetical questions but will not issue opinions on the ethical conduct of specific forensic psychiatrists or about actual cases. The Academy, through its Ethics Committee, or in any other way suitable, is available to the local or national committees on ethics of the American Psychiatric Association, to state licensing boards or to ethics committees of psychiatric organizations in other countries to aid them in their adjudication of complaints of unethical conduct or the development of guidelines of ethical conduct as they relate to forensic psychiatric issues. (AAPL 2005)

The AAPL ethics committee has recently resumed consulting with the APA ethics committee and the local district branches on ethics questions they may have pertaining to forensic psychiatry without giving an opinion on the ethics case itself. For instance, in the past when a forensic psychiatrist was accused of being rude, questions of how to assess for rudeness surfaced. The ethics committee responded that it was important to distinguish between actual rudeness via name-calling and being demeaning versus misperceived rudeness such as probing areas the person might prefer not to discuss, being skeptical of information provided, and wanting to obtain corroborating evidence. The latter examples are an essential part of a forensic examination in which certain information may be crucial for a meaningful assessment, and the possibility of malingering must be evaluated. These are not examples of rudeness. Forensic assessments in that regard differ from ordinary treatment assessments in which information can be obtained later in treatment, and malingering, while possible, is less common. Such distinctions were helpful and demonstrate how the AAPL ethics committee can assist the APA ethics committee in issues that arise in the forensic realm.

The first AAPL ethics guidelines were adopted in 1987, and there have been significant changes over the years, with the last revision adopted in 2005. The original ethics guidelines required forensic psychiatrists to be both unbiased and objective, which Diamond (1959) argued would be impossible for anyone to achieve. As he stated, all of us have our biases. For example, in criminal cases some identify with the prosecution. They want those breaking the law to be locked up, in order to be punished and because they could be dangerous and reoffend. Some alternatively identify with the defense and want to rescue those accused. They may offer reasons to side with the defendant such as concern for inadequate representation by an overworked public defender, for lacking mental health treatment resources for a chronic illness, or for suffering abuse or neglect as children. Hopefully, most of us are not set inflexibly on the extremes of this continuum, but it is clear that we all have our biases. It is neither helpful nor honest to pretend they do not exist. The challenge as forensic psychiatrists is to try to overcome our inevitable biases to reach as objective an opinion as possible.

Similarly, in the civil area, some of us are biased in favor of plaintiffs who may have suffered a severe injury that interferes with their functioning. We may feel they need help, and a wealthy insurance company can afford to pay regardless of whether legal technicalities are met. We may be prone to believe what plaintiffs tell us uncritically. On the other side, we may not want to reward malingering by giving plaintiffs advantages they do not deserve. Also, malingering costs all of society by increases in insurance rates. We may believe little of what plaintiffs tell us and think there almost always is gross exaggeration if not downright malingering. Most of us again likely lie at different points in that continuum which may be subject to change depending on time and circumstance.

Diamond then went on to say that in the unlikely event we have no bias at all in a case, once we reach an opinion we will want to advocate for our opinion and be biased in favor of the opinion we had reached. Diamond thought objectivity itself also was an impossible feat.

AAPL in revising this part of the ethical guidelines agreed that bias was inevitable because it is not volitional. It is true for all who do forensic work though not all organizations or practitioners are insightful or honest enough to admit it. AAPL replaced the requirement of being unbiased with a requirement to be honest—analogous to the Appelbaum requirement for truth-telling. But AAPL did not agree with Diamond about the impossibility of objectivity. Instead, AAPL thought it important for forensic psychiatrists to work to overcome biases resulting in the ethics guideline for striving for objectivity and to reach an objective opinion nonetheless.

AAPL ETHICS GUIDELINES (LAST REVISED 2005)

The main sections of the AAPL ethics guidelines are reprinted as follows:

1. *Preamble*: The American Academy of Psychiatry and the Law (AAPL) is dedicated to the highest standards of practice in forensic psychiatry. Recognizing the unique aspects of this practice, which is at the interface of the professions of psychiatry and the law, the Academy presents these guidelines for the ethical practice of forensic psychiatry.
2. *Confidentiality*: Respect for the individual's right of privacy and the maintenance of confidentiality should be major concerns when performing forensic evaluations. Psychiatrists should maintain confidentiality to the extent possible, given the legal context. Special attention should be paid to the evaluee's understanding of medical confidentiality. A forensic evaluation requires notice to the evaluee and to collateral sources of reasonably anticipated limitations on confidentiality. Information or reports derived from a forensic evaluation are subject to the rules of confidentiality that apply to the particular evaluation, and any disclosure should be restricted accordingly.
3. *Consent*: At the outset of a face-to-face evaluation, notice should be given to the evaluee of the nature and purpose of the evaluation and the limits of its confidentiality. The informed consent of the person undergoing the forensic evaluation should be obtained when necessary and feasible. If the evaluee is not competent to give consent, the evaluator should follow the appropriate laws of the jurisdiction.
4. *Honesty and Striving for Objectivity*: When psychiatrists function as experts within the legal process, they should adhere to the principle of honesty and should strive for objectivity. Although they may be retained by one

party to a civil or criminal matter, psychiatrists should adhere to these principles when conducting evaluations, applying clinical data to legal criteria, and expressing opinions.

5. *Qualifications*: Expertise in the practice of forensic psychiatry should be claimed only in areas of actual knowledge, skills, training, and experience.

The AAPL ethics guidelines have a commentary on each section that elaborates and provides supplementary information. Below are some important forensic issues excerpted from the commentary section.

In the preamble the commentary includes:

> Psychiatrists in a forensic role are called upon to practice in a manner that balances competing duties to the individual and to society. In doing so, they should be bound by underlying ethical principles of respect for persons, honesty, justice, and social responsibility. However, when a treatment relationship exists, such as in correctional settings, the usual physician-patient duties apply.

In the commentary on confidentiality section it includes:

> At the beginning of a forensic evaluation, care should be taken to explicitly inform the evaluee that the psychiatrist is not the evaluee's 'doctor.' Psychiatrists have a continuing obligation to be sensitive to the fact that although a warning has been given, the evaluee may develop the belief that there is a treatment relationship. Psychiatrists should take precautions to ensure that they do not release confidential information to unauthorized persons.

The consent section of the commentary includes the following:

> Absent a court order, psychiatrists should not perform forensic evaluations for the prosecution or the government on persons who have not consulted with legal counsel when such persons are: known to be charged with criminal acts; under investigation for criminal or quasi-criminal conduct; held in government custody or detention; or being interrogated for criminal or quasi-criminal conduct, hostile acts against a government, or immigration violations. Examinations related to rendering medical care or treatment, such as evaluations for civil commitment or risk assessments for management or discharge planning, are not precluded by these restrictions. As is true for any physician, psychiatrists practicing in a forensic role should not participate in torture.
>
> Consent to treatment in a jail or prison or in other criminal justice settings is different from consent for a forensic evaluation.

In the honesty and striving for objectivity section the commentary includes the following:

> Honesty, objectivity and the adequacy of the clinical evaluation may be called into question when an expert opinion is offered without a personal examination. For certain evaluations (such as record reviews for malpractice cases), a personal examination is not required. In all other forensic evaluations, if, after appropriate effort, it is not feasible to conduct a personal examination, an opinion may nonetheless be rendered on the basis of other information. Under these circumstances, it is the responsibility of psychiatrists to make earnest efforts to ensure that their statements, opinions and any reports or testimony based on those opinions, clearly state that there was no personal examination and note any resulting limitations to their opinions.
>
> Contingency fees undermine honesty and efforts to attain objectivity and should not be accepted. Retainer fees, however, do not create the same problems in regard to honesty and efforts to attain objectivity and, therefore, may be accepted.
>
> Psychiatrists who take on a forensic role for patients they are treating may adversely affect the therapeutic relationship with them. Forensic evaluations usually require interviewing corroborative sources, exposing information to public scrutiny, or subjecting evaluees and the treatment itself to potentially damaging cross-examination. The forensic evaluation and the credibility of the practitioner may also be undermined by conflicts inherent in the differing clinical and forensic roles. Treating psychiatrists should therefore generally avoid acting as an expert witness for their patients or performing evaluations of their patients for legal purposes.
>
> Treating psychiatrists appearing as "fact" witnesses should be sensitive to the unnecessary disclosure of private information or the possible misinterpretation of testimony as "expert" opinion. In situations when the dual role is required or unavoidable (such as Workers' Compensation, disability evaluations, civil commitment, or guardianship hearings), sensitivity to differences between clinical and legal obligations remains important.

AAPL also has a section on Questions and Answers (revised in 2013) that further flushes out the meaning of the

guidelines. The Questions and Answers as well as the guidelines with the full commentary can be accessed at http://aapl.org/ethics.htm.

AAPL's guidelines were developed specifically for forensic psychiatry and address important, relevant issues. However, they exclude or are vague regarding issues for which consensus could not be obtained. They represent guidelines for good practice, though in reality most AAPL guidelines have reached a level of general agreement and as such represent a consensus as to what is required for ethical practice. The AAPL guidelines are aspirational and not enforced as such but can help clarify ethical questions and positions to enable assessment of actions of a forensic psychiatrist by the state medical boards or the local APA district branches enforcing the APA ethics Annotations. In this way, the AAPL ethics guidelines can be enforced. Ethics complaints are referred to the APA district branch, which has the option to consider them, or to another analogous body for foreign members. AAPL members who belong only to the American Academy of Child and Adolescent Psychiatry have ethical complaints against them referred to that organization, which in turn refers complaints to state licensing boards.

The APA district branch ethics committees, who actually conduct ethics investigation hearings involving APA members accused of an ethics violation, increasingly consider the AAPL guidelines to clarify APA Annotations. The high response rate in surveys, and the fact that an overwhelming majority of forensic psychiatrists in surveys indicate they have encountered ethical problems, belies any aspersions that forensic psychiatrists are unconcerned about, or insensitive to, ethical problems.

A survey of AAPL members (Weinstock et al. 1991) showed support (in decreasing order) for the following additional guidelines that are not currently part of the official guidelines:

1. Medical and psychiatric ethics remain a consideration when performing a forensic evaluation.
2. The forensic psychiatrist should not distort data.
3. Sex between a forensic psychiatrist and an evaluee is unethical so long as the case remains in litigation.
4. Because of the seriousness of the matter, an opinion should not be given in a death penalty case without a personal examination regardless of whether court decisions hold such testimony permissible.
5. As a physician, a forensic psychiatrist owes some responsibility both to an evaluee and society, regardless of who pays the fee.

PRINCIPLES OF MEDICAL ETHICS WITH ANNOTATIONS ESPECIALLY APPLICABLE TO PSYCHIATRY RELEVANT TO FORENSIC PSYCHIATRY

The APA has developed Annotations that were revised to include the latest version of the AMA Principles of Medical Ethics (American Psychiatric Association 2013). They elaborate on issues and situations especially applicable and relevant to psychiatric practice.

In reference to the APA Annotations, Appelbaum (1992) has stated that the Annotations suffer insofar as "they are generated on an ad hoc basis, as an issue rises to the surface in the APA rather than in a systematic effort to elaborate an ethical code." Although many are relevant, they are not specifically directed to the forensic setting. Moreover, as mentioned by Appelbaum, some rules are "so general as to create no boundaries at all." Nonetheless, many of the Annotations are relevant to forensic psychiatry.

The existing Annotations are enforced through the APA district branches. They are important for all psychiatrists, and ignorance is not a legitimate excuse. An allegation of an ethics violation against an APA member is investigated by the local district branch of the APA, which holds hearings and recommends sanctions if an ethical violation is found. Sanctions include admonishment, reprimand, suspension, and expulsion from the APA. Expulsions and more than very brief suspensions also are reported to the National Practitioners Data Bank since September 1, 1990. The Data Bank contains records of medical professionals, psychotherapists, and dentists who have been successfully sued (even if settled), whose licenses have been revoked or suspended, or who have been sanctioned by a hospital, medical group, or health plan with a peer review system (with privileges suspended or removed). In addition, the Ethics Committee of the APA district branches can report offending member psychiatrists to state licensing boards. If a member resigns while the case is under investigation, this fact can be made public in an APA publication if the allegation is serious.

The section numbers in the Annotations correspond to those numbers of the AMA Principles. Relevant annotations that address forensic psychiatric issues are as follows:

Section 1

Annotation 4 prohibits physician participation in a legally authorized execution. This section had been interpreted solely as prohibiting administering lethal injections. The AMA has already passed resolutions affirming that it is unethical for physicians, regardless of their personal views of capital punishment, to participate in legally authorized executions, except to certify death. They have stated that involvement short of the death penalty process itself is ethical. They even say the controversial testimony about aggravating circumstances at the penalty phase of a capital trial is ethical, as is the testimony of mitigating circumstances. They do not consider it ethical to treat someone for the purpose of making them competent to be executed. But it is ethical to treat them to relieve suffering or maintain prison security even if that is likely to result in a prisoner becoming competent to be executed. The intent of the psychiatrist is the determining factor here.

Section 2

Annotation 1 states that sexual activity with a current or former patient is unethical because of the inherent inequality in the doctor–patient relationship that may lead to exploitation. Annotation 2 states that the psychiatrist should diligently guard against exploiting information furnished by the patient and should not use the power afforded to him or her to influence the patient in ways not directly relevant to treatment goals. Annotation 3 states that psychiatrists who practice outside their areas of expertise should be considered to be practicing unethically. Annotation 4 states that in situations in which psychiatrists, because of mental illness, jeopardize the welfare of their patients and their own reputations and practices, it is ethical and even encouraged for another psychiatrist to intercede. Annotation 5 states that like all medical services, psychiatric services are dispensed in the context of a contractual arrangement with the patient binding on the physician as well as on the patient, and the provisions of such a contract should be established explicitly. Annotation 7 states that it is unacceptable to engage in fee splitting—that is, providing supervision or administration to other physicians or nonmedical people for a percentage of their fees or gross income. It is ethical though in a team of practitioners or a multidisciplinary team to receive income for administration, research, education, or consultation if based on a mutually agreed upon set fee or salary open to renegotiation as time demand changes.

Section 3

Annotation 1 indicates that when illegal activities bear directly upon practice, it would be self-evident that such a psychiatrist would be ethically unsuited to practice. Protesting social injustice probably would not bear on either the psychiatrist's image or his or her ability to treat patients ethically and competently. Although no prior assurance about any illegal activity could be given, it is conceivable that an individual could violate a law in such circumstances without being guilty of unethical professional behavior.

Section 4

Annotation 1 requires the protection of patient records, even the identification of the person as a patient. Annotations 2 and 5 involve confidentiality and its limitations and the exercise of caution when disclosing sensitive patient information. Annotation 5 states that the disclosure of sensitive material like fantasy material and sexual orientation is usually unnecessary. Annotation 3 requires adequate disguise to protect anonymity in teaching and writing. Annotation 4 includes a duty in consultations to alert any nonphysician consultant to the duty of confidentiality.

Annotation 6 directly is applicable to forensic psychiatry and states that if individuals are examined for security purposes, determining suitability for certain jobs, or determining legal competence, the nature, purpose, and lack of confidentiality of the examination must be explained at the onset to the examinee. Although Annotation 6 does not specifically cover all forensic examinations, AAPL ethical guidelines require such explanations whenever lack of confidentiality is involved. Annotation 9 applies if psychiatrists are ordered by the court to reveal patient confidences. They may comply or ethically hold the right to dissent within the framework of the law. If in doubt, they should respect the right of the patient to confidentiality and unimpaired treatment and should reserve the right to raise the question of adequate need for disclosure. If case disclosure is required by the court, then the right to disclose only information relevant to the legal question at hand may be requested.

Annotation 13 states that "psychiatric evaluations of any person charged with criminal acts prior to access to, or availability of, legal counsel should not be performed except for rendering of care for the sole purpose of medical treatment." This is also an AAPL requirement in the commentary under section III Consent in the AAPL ethics guidelines. Annotation 14 states that sexual involvement between faculty members or supervisors and trainees or students may be unethical because an abuse of power can occur that takes advantage of inequalities in the working relationship.

Section 6

Annotation 2 states that it is ethical to refuse to provide psychiatric treatment to anyone who cannot be diagnosed in the psychiatrist's opinion with a mental illness amenable to psychiatric treatment.

Section 7

Annotation 3 refers to public figures or others who have disclosed information about themselves through the public media. It says it is ethical to share with the public opinions about psychiatric issues in general under such circumstances. But it is unethical to express an opinion about such an individual without a personal examination and proper authorization for such a statement. Annotation 4 concludes that a personal examination of the patient is required prior to certifying a patient for involuntary treatment. Annotation 5 states psychiatrists should not participate in torture.

Section 8

This section states that when caring for patients, responsibility to the patient is paramount. Annotation 1 clarifies that relationships with outside organizations can affect patient care. Annotation 2 says when these conflicts exist, psychiatrists must resolve them in a way believed to benefit patients. Annotation 3 states when these relationships conflict with patient needs, the patient or decision maker should be informed. Annotation 4 states when patients are informed of treatment options in order to promote an

informed treatment decision, the options presented should include those not available from the psychiatrist or affiliated organization.

OPINIONS OF THE APA ETHICS COMMITTEE ON THE PRINCIPLES OF MEDICAL ETHICS RELEVANT TO FORENSIC PSYCHIATRY

Some published Opinions of the APA Ethics Committee on the Principles of Medical Ethics also are relevant (American Psychiatric Association 2013, 2014). The Opinions relevant to forensic psychiatry are listed under G followed by a number and then by a letter. The number refers to the corresponding principle of medical ethics. Below are some of the Opinions apropos to the practice of forensic psychiatry.

Section 1

Opinion G1b makes it clear that giving a lethal dose of a sedative to a prisoner in a legal execution is unethical because a physician is a healer, not a killer. Opinion G1c clarifies that it is ethical to provide a competency examination before the execution of a felon so long as the prisoner is fully informed of the purpose of the examination and has legal representation. Opinion G1d states it would be highly questionable to evaluate a family member who is a plaintiff in a lawsuit, because it is highly likely the relationship would influence the psychiatrist as well as the relative's presentation. Also, any attempt to testify would be vulnerable to challenge. Providing competent medical service would be too difficult in this situation. Opinion G1e clarifies that the same ethical principles apply in a diagnostic/consultative relationship. An example is an evaluation for an insurance company.

Section 4

Opinion G4a states it is not ethical for a hospital employee to perform a competency of a patient for the purpose of assisting his or her hospital employer to collect patient charges, because of a conflict of interest. Opinion G4b clarifies that developing a speculative psychological profile for someone who committed gruesome mass homicides is not unethical. If a psychiatrist believes the profile is that of one of his or her patients, he or she should strongly urge the patient to go to the police, perhaps with the assistance of an attorney. If the patient refuses, the psychiatrist can notify the police. If the attacks are past history, the guidelines advise only encouraging a patient to turn himself or herself over to the authorities, but it may be prudent to tell the patient to retain an attorney first so that his or her legal rights and welfare will not be ignored. Opinion G4c clarifies that it is ethical to render an opinion for an insurance company regarding the suicide of a patient based on a record review despite having no opportunity to examine the patient. Section Opinion G4d raises the issue of a psychiatrist who treated a member of a murdered prominent family, testified in court, and was later asked by a television company to be a consultant for a movie about the killing. The Opinions state it does not foster a good image but can be ethical if nothing new and no new insights other than those made public at the trial are revealed. It is unclear whether this admonition applies, though, to a nontreating forensic psychiatrist, but it is likely to apply to information not released in open court. Opinion G4e clarifies that it is ethical to evaluate a prisoner for the state and determine that the prisoner requires involuntary hospitalization if a proper psychiatric examination is performed and the nature, purpose, and lack of confidentiality of the exam are explained. Opinion G4f clarifies that it is unethical for a treating psychiatrist to participate in adversarial evaluations of their convicted sex offender patients around questions of whether they should later be screened for possible involuntary civil commitment as sexually violent predators, unless at the outset of treatment the dual relationship to them and the prison system were explained, and it was explained that their records could later be used to determine whether they later will be civilly committed as sexually violent predators.

Section 7

Opinion G7a states that consulting to the Catholic Diocese about marriage annulments regarding the competence of church members to request such an annulment is ethical without a personal examination with only a review of reports and other information. Requiring consultants always to conduct a personal examination if asked by various medical, social, and rehabilitative agencies for opinions would be impractical and would prevent their obtaining the benefits of psychiatric consultation. Opinion G7b discusses testifying for the state in a criminal case about the competency of the defendant based on medical records without examining the defendant or having his or her approval to render an opinion. The Opinion states that Section 7, Annotation 3, was developed to protect public figures from psychiatric speculation harmful to public figures and the psychiatric profession, and not to protect criminal defendants. This opinion, however, could be interpreted as not necessitating the more stringent requirement of AAPL's ethical guidelines. AAPL requires a personal examination if at all possible and creates an affirmative obligation to indicate the limitations of any opinion if given without such a personal examination.

One problem with the APA Annotations and Opinions is that they do not cover any issues in any systematic way and are not based on any underlying ethical principles other than the AMA Principles of Medical Ethics. They also are not specifically directed toward forensic psychiatry. They respond only to inquiries about actual cases (Appelbaum 1992). The APA lacks direct jurisdiction over the ethical improprieties of nonmembers, but their guidelines still are relevant for court and licensing board actions and are

relevant to all who practice forensic psychiatry whether or not they are APA or AAPL members.

RELEVANT ETHICAL GUIDELINES OF OTHER PROFESSIONAL ORGANIZATIONS

The American Academy of Forensic Sciences (AAFS) also has an enforceable code of ethics, important even if limited in scope. The code precludes professional or personal conduct adverse to the best interests and purposes of AAFS that includes the following: misrepresentation of education, training, experience, area of expertise, or one or more criteria for membership; material misrepresentation of data upon which an expert opinion is based; and making public statements appearing to represent the position of AAFS without first obtaining the specific permission of the board of directors. Distortion of data addressed by AAFS is not specifically addressed by AAPL, but could be considered under the section on honesty (see AAPL guidelines). AAPL's Section V on qualifications does specifically address the need for accurate presentation of qualifications and experience. It is less clear whether these issues are covered by the APA Annotations, unless Section 2, referring to dealing honestly with patients and colleagues, would also be interpreted to include courtroom testimony, or Section 7 regarding a responsibility to participate in activities contributing to an improved community would apply. Section 1 on competent medical service is also relevant.

Other related organizations have developed ethical criteria for forensic participation. These include the American Psychological Association and the National Organization for Forensic Social Work (American Psychological Association 2010; National Organization for Forensic Social Work 2011).

CONTROVERSIAL ETHICAL ISSUES

An ethics survey of forensic psychiatrists showed almost all had encountered ethical problems in their forensic work. The "hired gun" problem was considered to be the greatest ethical problem (Weinstock 1986, 1988). However, without knowing the forensic psychiatrist's motives, it is difficult to distinguish honest bias, sometimes even unconscious, from that of a "hired gun." Moreover, it is too easy sometimes for forensic psychiatrists who consider their position "right" to confuse an honest difference of opinion with the problem of the expert on the other side being a "hired gun." AAPL has developed systematic ethics guidelines for the practice of forensic psychiatry. The principles were first developed by Jonas Rappeport, and refined, modified, and developed by Henry Weinstein, the section on honesty and striving for objectivity revised by Weinstock in the 1995 revision.

AAPL has been criticized for not enforcing its own ethical guidelines (Halpern 1990; Appelbaum 1992). Instead, it relies on the APA for enforcement. Forensic psychiatry's recognition as a subspecialty arguably makes medical ethics even more relevant. AAPL has developed procedures for peer review of transcripts of psychiatric testimony, because there is controversy regarding whether such issues should or would be covered in ethical guidelines (Weinstock et al. 1991; Appelbaum 1992). AAPL's ethical guidelines supplement the APA Annotations. Peer review enables additional professional self-regulation. However, because it is currently voluntary, such peer review is likely to be avoided by those most in need of it. Despite the criticisms, the ethical guidelines nevertheless are a very important development. They were initially passed in 1987, and last revised in 2005.

Some issues in forensic psychiatry remain controversial. The death penalty, for example, produces conflict in forensic psychiatry, as it does generally in American society, with the additional factor of the forensic psychiatrist being a physician. All other Western democracies have abolished the death penalty. In capital cases, the legal system often asks forensic psychiatrists to examine defendants and evaluate various legal issues, including various competencies, mental state at the time of the offense, dangerousness, and aggravating and mitigating circumstances. It can be argued in one extreme that psychiatric assessments of these forensic issues are shared by both capital and noncapital cases and do not differ. At the other extreme, some psychiatrists question the ethical propriety of providing consultation to the prosecution at any stage of a capital case (Leong et al. 2000). There are many intermediate positions.

Although there is some correlation between a psychiatrist's personal views of the death penalty and their professional views about the proper role of the forensic psychiatrist in such cases, the two are not the same. It is possible to oppose capital punishment as a citizen but to participate in the process short of the actual killing because the psychiatrist believes it does not violate professional ethics. It is not the psychiatrist's professional role to question current law, the opinion is sufficiently removed from the killing process, and such a view is supported by current professional ethical guidelines. Forensic psychiatrists who support the death penalty as a citizen can still believe it violates their view of appropriate professional medical ethics to participate in some or all forensic roles. Forensic psychiatrists who oppose the death penalty also can choose to participate honestly in cases in which they think their involvement could be helpful, even if the opposite result sometimes occurs (Diamond 1990, 1992; Foot 1990). The APA has taken a position against treating defendants incompetent to be executed if the purpose is to make them competent to be executed.

ETHICAL PRACTICE

According to the theory of virtue ethics, ethical guidelines and even knowing what is right does not necessarily lead to doing the right thing. It is necessary to wish to be ethical. Knowledge will not necessarily affect the behavior of the "hired gun." However, it is often difficult to know whether a forensic psychiatrist truly has an idiosyncratic belief, has

been insensitive, or has been dishonest. Ethics committees could be placed in an untenable position of having to determine the intent of an alleged offending action. Forensic psychiatrists should not unfairly be blamed for the problems of the adversarial legal system.

Guidelines can help clarify what is ethical. However, the best insurer of ethical conduct must be the integrity of the professional persons themselves who, in forensic psychiatry, face the challenge of confronting and balancing many conflicting values. These challenges are not unique to forensic psychiatry, but are more complex than in the relatively uncomplicated treatment context, and are unique insofar as the interface is with the legal system. These challenges can provide some of the enjoyment of being a forensic psychiatrist. However, organizations that do enforce ethics requirements and provide sanctions should be aware of the complex balancing of values involved in forensic psychiatric practice. Sanctions should not be imposed if there is no general consensus, and legitimate differences of opinion about a specific ethics dilemma could apply.

What makes it right: Foundations for professional ethics

RICHARD ROSNER*

INTRODUCTION

One of the hallmarks of a profession is that its members share an ethical code, setting out the conduct that they regard, collectively, as acceptable. The professions are, however, unlikely to set forth its foundation—that is, what makes it right. The following is meant to stimulate thought about this gap.

A professional ethical code is an example of normative ethics, the study of the standards used for the ethical evaluation of conduct. A justification of a professional ethical code is an example of meta-ethics, the study of the meaning of ethical terms, such as "right." It is possible, but unsatisfying, to have an ethical code that is not justified, a normative ethics that is not connected to meta-ethics.

The leading nonjustifying explanations of all ethical codes are ethical relativism and subjectivism; the main justifications for ethical codes are (1) divine commandment, (2) natural law, (3) traditional folk ways, (4) consequentialism, (5) deontology, and (6) feminist ethics.

The two nonjustifying explanations for ethical codes are ethical relativism and subjectivism/emotivism.

ETHICAL RELATIVISM

Ethical relativism starts from the position that there are many ethical codes, often disagreeing about what is right. For ethical relativists, a specific professional ethical code is right because the members of its specific profession internally regard it as so. The Catholic clergy, for example, may agree that abortion is wrong, but ethical relativism states that all that makes it wrong for them is their internal agreement; obstetricians and gynecologists may agree that abortion is right, but similarly, it is only right for them because of their internal agreement. In ethical relativism, there is no external, objective standard of wrong and right and no method of adjudicating between them.

Among the criticisms of ethical relativism is that it is based on unsound reasoning. An alternative position is that it is possible that one of the ethical justifying theories is correct, but that no one yet knows this. There was once a time, for example, when some people thought that the sun moved around the earth (geocentrism) and some other people thought that the earth moved around the sun (heliocentrism). It would have been possible, but wrong, to conclude that neither theory was right. Some critics of ethical relativism suggest parallels for ethical theory, while others suggest that an as-yet-unknown correct ethical theory will emerge in future, even if no existing one is correct (Frankena 1973, 109–110; Rachels 2003, 16–31).

SUBJECTIVISM/EMOTIVISM

In its twentieth-century formulation, subjectivism is called emotivism, regarding ethical statements merely as expressions of subjective emotional states. Saying, for example, that "Abortion is bad!" or "Abortion is good!" is regarded as tantamount to saying "Abortion: phooey!" or "Abortion: hooray!" Such expressions also function as imperatives—that is, ordering people to refrain from acting in a certain way ("phooey" = do not get an abortion) or to act ("hooray" = get an abortion). For ethical subjectivists, there is no justification for any ethical code and no objective standard for evaluation; disagreements about whether an act or principle is right are like disagreements about whether a particular aesthetic style is beautiful.

Critics of ethical subjectivism find it unsatisfying because (1) it precludes a role for rationality in ethical decision making and (2) it makes emotional manipulation, such as

* This chapter is reprinted with permission from John Wiley & Sons, Ltd. from Richard Rosner's part of the following article: Grounds A, Gunn J, Myers WC, Rosner R, and Busch KG. 2010. Contemplating common ground in the professional ethics of forensic psychiatry. *Criminal Behaviour and Mental Health* 20(5):307–322.

advertising or propaganda, a legitimate means of influencing ethical codes (Rachels 2003, 32–47). The six justifying explanations for ethical codes are (1) divine commandment, (2) natural law, (3) traditional folk ways, (4) consequentialism, (5) deontology, and (6) feminist ethics.

DIVINE COMMAND

According to this view, popular among Christian, Muslim, and Jewish fundamentalists, something is right because God commanded it. The justification for the Ten Commandments, for example, is that God commanded obedience to them.

Critics of this theory say that it makes God's commands arbitrary. In one commandment, for example, God says: "honour your father and your mother." Is it God's command itself that makes it right for us to honor our parents? If it is, then, had God ordered us to dishonor them, then that behavior would be right. The suggestion that God's commands are purely arbitrary is rarely comfortable for religious people; they are likely to suggest an alternative, e.g., that in His wisdom, God knows what is right for us. If this latter view is correct, however, then it is not God's command per se that makes something right (Frankena 1973, 28–30; Rachels 2003, 48–53).

NATURAL LAW

The classic statement of this ethical theory lies with St Thomas Aquinas, in Europe's Middle Ages. Greatly oversimplified, it holds that God endowed us with the rational capacity to derive ethical rules from observations of the empirical facts of the world we live in. For natural law ethicists, there is a necessary connection between reason and what is right. Such an ethical code is not arbitrary and must benefit the persons who subscribe to it. Natural law ethicists might, for example, observe the fact that human genitalia enable human reproduction and conclude that it is ethical to use them for reproductive ends, but not for nonreproductive ends (e.g., for pleasure).

Critics of this approach say that the theory is not logically sound—"natural facts" do not lead to "natural oughts"—and that different persons looking at the same facts may come to different conclusions. To pursue the genitalia example, others might observe that human genitalia enable both reproduction and pleasure and conclude that it is ethical to use them for both (Rachels 2003, 53–62).

TRADITION

According to this view, an ethical code is right because people who adhere to it have always regarded it as right. The Hippocratic Oath recites one ethical code of physicians. In this theory, what makes it right would be that Western doctors have accepted it for over 2000 years.

Critics of traditional ethics state that this theory precludes advances in ethical codes, as change could not be justified if tradition alone made a code right. Slavery and female disenfranchisement have been, and in some cultures still are, traditionally thus regarded as right. Traditional ethics fixes ethics forever, preventing the growth and development of ethical standards for human conduct (Rachels 2003, 18).

CONSEQUENTIALISM (UTILITARIANISM)

Called utilitarianism in nineteenth-century England, consequentialism holds that what makes an ethical code right is that compliance with it produces the greatest good for the greatest number of persons. For consequentialist ethicists, there is a necessary connection between goodness and rightness, and the ends justify the means. Given two or more different courses of action, the course that produces the most good for the most people is the right one.

Critics of consequentialism state that it may conflict with justice and individual rights (Frankena 1973, 34–43; Rachels 2003, 91–116).

DEONTOLOGY

This view asserts that something other than desirable consequences makes an ethical code right. Kant was its most famous exponent. According to him, some things are contingently or hypothetically right (because they lead to a desired outcome in fact) and some categorically right (because right in themselves). Kant called his criterion of being right "the categorical imperative." It can be formulated as a criterion to act always so that the maxim of your action can be a universal and eternal rule for everyone, or the converse of this. If you pay your debts, for example, the maxim of your action is that it is right to pay debts, and the permanent and universal rule is that everyone should always pay their debts; this is a non-self-defeating maxim that can be followed. If, by contrast, you steal from others, the maxim of your action is that it is right to steal, but if this maxim were to be made into an enduring rule for everyone, society would self-destruct, making it a self-defeating maxim that cannot be followed.

Critics of deontology say that it may lead to incompatible ethical rules in irresolvable conflict, e.g., having one rule always to tell the truth and another never to endanger human life. What do you do in occupied Holland if you are hiding Anne Frank and her family when the Nazis knock on the door and ask if you know where they are (Frankena 1973, 23–33; Rachels 2003, 117–140)?

FEMINIST ETHICS

Most ethical theorists in the Western tradition have been men. Twentieth-century feminists argued that there are sufficient female–male differences that a feminist ethics is required. Men, they suggest, are interested in abstract and impersonal principles, as just described, while they are interested in caring and personal relationships.

SUMMARY

My view is that there is a gap in professional ethical codes in their failure to offer grounding for the ethical precepts that they offer. Although there are no explanations and no justifications that are beyond criticism, it may be that the drafters of professional ethical codes are avoidant of revealing the lack of meta-ethical foundations for their normative ethical prescriptions.

Critics note that this theory is not as detailed or complete as the others; if so, this may be due to its relatively recent origin (Rachels, 2003, 160–172).

Liability of the forensic psychiatrist

DANIEL BONNICI, KATE BOLTON BONNICI, ROBERT WEINSTOCK, AND THOMAS GARRICK

INTRODUCTION

Potential legal causes of action against psychiatrists practicing in a general clinical context include medical malpractice, other types of negligence, intentional torts, federal civil rights law (statutory causes of action), and medical board complaints. Forensic psychiatrists operate within a narrower ambit than general psychiatrists, with different employers and different tasks. Because forensic psychiatrists have a particular and proscribed role, some of the liability concerns inherent in a broader clinical psychiatric practice are constrained. Because forensic psychiatrists are functioning as psychiatrists and not attorneys, they are not liable for not knowing the law. However, forensic psychiatrists should become aware of existing legal theories and causes of action, usually by consulting with an attorney about the laws in the place the alleged action occurred, as laws and legal criteria can vary widely by jurisdiction. In considering questions of legal liability for medical malpractice and negligence claims arising out of medical practice, which generally involve questions of fact, one must first resolve the following questions: (1) Who is the forensic client? (2) What is the forensic task? and (3) Is the psychiatrist immune from liability or prosecution?

OVERVIEW OF LEGAL LIABILITY

Broadly stated, the elements of negligence include a duty of care on the part of the defendant, breach of said duty, and such breach of duty must directly and proximately cause harm. Medical malpractice involves a legal claim similar to negligence, but requires an existing physician–patient relationship, and physicians are held to a "professional" standard. Less common causes of action include intentional torts such as defamation and intentional infliction of emotional distress. Defamation may be loosely defined as any statement (written or oral) that harms a person's reputation. Intentional infliction of emotional distress arises when a party acts intentionally or recklessly, with conduct that is extreme or outrageous, and the conduct causes severe emotional distress.

Medical board complaints constitute an additional area of concern for general and forensic psychiatrists. Recent data suggest that while malpractice claims against psychiatrists remain relatively low compared to other specialties, psychiatrists incur a higher proportion of medical board complaints filed against them (Reich and Schatzberg 2014).

WHO IS THE FORENSIC CLIENT?

Forensic psychiatrists practice in a variety of roles, including treating patients, completing court evaluations, providing independent medical evaluations, consulting, and teaching. Forensic psychiatrists may treat patients in a clinical setting, including prisons, where liability would be similar to general psychiatrists who are not forensically trained. Distinct liability issues arise depending on the given role. With regard to specifically forensic work, third parties may ask forensic psychiatrists to evaluate patients for a variety of reasons. Forensic psychiatrists may perform workers' compensation evaluations, mental state evaluations, and insurance-based evaluations. One growing field in both forensic psychiatry and other medical fields is the independent medical evaluation (IME), the development of which is generating new case law and additional avenues for lawsuits (Gold and Davidson 2007). In IMEs, discussed below, some duties arise to the third party who hires the psychiatrist, along with certain limited duties to the examinee.

Forensic psychiatrists also provide evaluations and testimony in both civil and criminal court cases, often at the request of the court. In such cases, psychiatric experts may be hired by attorneys representing one side in a dispute (theoretically more akin to an IME) or contracted by order of the court (which offers additional legal protections). Last, forensic psychiatrists provide consultations to psychiatrists or other medical professionals on issues that may arise in clinical practice. Forensic psychiatrists may consult with other psychiatrists or physicians regarding the legal

regulation of psychiatry, consult with professional societies, or consult with hospitals or medical staffs in peer review situations and/or on ethics committees (Willick et al. 2003). Determination of the forensic client, e.g., third-party, court, party to litigation, or other medical professional, is a critical first step in considering liability and legal consequences, because this relationship—alongside the task to be performed—undergirds the construction (or nonexistence) of a legally operative obligation, violation, or omission.

Duty and the absence of a physician–patient relationship

The question of with whom the forensic psychiatrist has a relationship determines what governing duty is involved and to whom such duty is owed. Traditionally, courts have narrowed the scope of duty in forensic work by focusing on whether a doctor–patient relationship existed (similar to what is required for malpractice liability for psychiatrists functioning in a treatment capacity), as determined by the specific facts of each case. Courts have frequently discussed physician–patient relationships in contractual terms, observing, as in *Osborne v. Frazor* (1968) that the relationship "is basically contractual and wholly voluntary, created by agreement, express or implied, and by its terms may be general or limited." As well, in *Lyons v. Grether* (1977), determination of the relationship "is a question of fact, turning on a determination of whether the patient entrusted his treatment to the physician and the physician accepted the case."

In *Davis v. Tirrell*, a 1981 case, the Supreme Court of New York dismissed an action by parents on behalf of their minor child arising out of an examination into whether the child was "handicapped" for a school report given to a third party. The parents later claimed that the evaluation should have been privileged health information. The court found that there was no plan to diagnose for treatment, nor to treat, and so no physician–patient relationship existed. However, the court noted that the student and his parents "sincerely believed" that a patient–physician relationship existed and "could have asserted their claim of privilege on the proceeding before the hearing examiner, and their failure to do so could be considered either as a waiver of the privilege or as a recognition that no physician–patient relationship existed." According to the court, due to the absence of a physician–patient relationship, the action was due to be dismissed.

IMEs: limited duty to patient?

In *Felton v. Shaeffer* (1991), the California Court of Appeals held that an independent medical examiner for an industrial medical center conducting a pre-employment physical examination had no duty to an examinee concerning the accuracy of a medical report. In that case, a prospective employee presented with elevated blood pressure after not taking his medication on the day of the exam. The doctor erroneously reported that he was not compliant with his antihypertensive medication and could make "no decision" on his suitability. The court found that there was no physician–patient relationship and so no duty existed to the examinee. The court found no actionable negligence, nor a viable medical malpractice claim, because no doctor–patient relationship existed. The court did point out that the duty was owed to the third party who contracted with the physician, but that "relationship" was not involved in the case.

In IMEs, even when there is no duty to treat or to diagnose correctly, there appears to be a gaining consensus among state courts that there is a duty to *not* cause harm in the exam itself. In *Mero v. Sadoff* (1995), the California court expanded on dicta from *Felton v. Schaeffer*. In *Mero*, an orthopedic evaluation during a workers' compensation evaluation included the patient being placed in "an apparatus" which caused "a total collapse and deterioration of the spinal fusion at L5 performed in May of 1990 … severe, permanent and disabling injuries as w[e]ll as great mental and physical pain, suffering and emotional distress." The court held that "even in the absence of a physician–patient relationship, a physician has liability to an examinee for negligence or professional malpractice for injuries incurred during the examination itself."

Additionally, in *Greenberg v. Perkins* (1993) the Colorado Supreme Court found that the trial court erred in stating that the doctor owed no duty to the patient because no doctor–patient relationship existed. In that case, Dr. Greenberg ordered a "functional capacity exam" (a physical exam) as part of his court-ordered evaluation, ultimately leading to worsening of an injury. The court found that Dr. Greenberg should have known such an exam carried significant risks, and he therefore owed a (limited) duty of care to the patient.

In *Martinez v. Lewis* (1998), the Colorado court further explains this duty with facts specific to a forensic psychiatry evaluation. In that case, the psychiatrist owed no duty to the patient for alleged misdiagnosis. Ms. Martinez was in a motor vehicle accident and claimed she contracted both psychiatric and neurologic conditions as a result. Her insurance company contracted with Dr. Lewis to evaluate the patient for such claims. After his evaluation, which included computerized tests, a patient interview, and a review of relevant records, he identified that the patient was "malingering." In holding that Dr. Lewis owed no duty of care to Ms. Martinez, the Colorado Supreme Court pointed out that the patient was not seeking treatment from Dr. Lewis, that no harm or injury was alleged from the examination itself, nor was he alleged to have made misrepresentations to the public. Therefore, he owed no additional duty to the patient.

More recently, in *Harris v. Kreutzer* (2006) the Supreme Court of Virginia held that a psychologist who performed an IME under the relevant Virginia statute was considered a health-care provider and had a limited doctor–patient relationship with the "patient" and was subject to the medical malpractice standard in that case. The limited relationship included a duty not to harm the patient during the evaluation but did not include a duty to diagnose or to treat.

Duty to a third party?

Even if there is no physician–patient relationship, a duty of care may run from the forensic psychiatrist to the third party who engaged the psychiatrist's services. For example, in *Hafner v. Beck* (1995), the Arizona court held that a forensic psychologist had a duty to the third party who contracted with her, but not to the person she examined. In that case, Ms. Hafner was evaluated by Dr. Beck for a workers' compensation claim. Dr. Beck completed an evaluation and concluded that the patient had no psychological injury and required no psychological treatment. The court concluded that Dr. Beck owed no duty of care to the patient, reasoning that "[i]f an IME practitioner's evaluations, opinions, and reports could lead not only to vehement disagreement with and vigorous cross-examination of the practitioner in the claims or litigation process, but also to his or her potential liability for negligence, the resulting chilling effect could be severe." The court noted as well that "assuming that Beck's conduct fell below the standard of care for psychologists, it was a breach of duty owed to [the insurance company], not to Hafner."

WHAT IS THE FORENSIC TASK?

The second question to consider in the context of possible legal liability for the more common categories of negligence and medical malpractice is the nature of the forensic task being performed. The specific task is relevant because different duties are owed to different parties in different circumstances.

The two principle forensic tasks include consultation and testimony. A consultation may include an examination and/or review of other sources of information regarding the person evaluated. Certain consultations may not involve an examination and would entail fewer duties. Peer reviews, ethics consultations, and postmortem suicide evaluations may only include post-hoc chart reviews, but also could involve significant financial and emotional considerations. The American Academy of Psychiatry and the Law (AAPL) ethics guidelines (2005) and the American Medical Association (AMA) (1999) opinion 10.03 should be followed even in these cases. These include striving for objectivity, maintaining confidentiality, and adhering to the principle of obtaining informed consent (when applicable).

Expert opinion testimony in a judicial proceeding is the other major category of forensic work and would generally occur after an evaluation in civil or criminal capacities. Examples include evaluations of sanity of criminal defendants for the purposes of both appropriateness for trial or culpability, and evaluating fitness for parenting in child custody cases.

INTENTIONAL TORTS

Intentional torts, including but not limited to fraud (such as the intentional misrepresentation of qualifications for the purpose of employment), intentional infliction of emotional distress, defamation, and physical and sexual assault/battery, generally do not require a threshold physician–patient relationship and so remain possible legal causes of action arising out of interactions with patients in a forensic setting.

Theoretically, a forensic psychiatrist could be sued for intentional infliction of emotional distress if an evaluation was conducted in a manner intentionally designed to be emotionally damaging. Likewise, a forensic psychiatrist who intentionally misrepresents his or her qualifications for the purpose of obtaining employment could be sued by his or her employer. Intentional torts are generally not covered by medical malpractice insurance.

CLAIMS ARISING UNDER FEDERAL CIVIL RIGHTS LAW

Federal civil rights law, codified in the U.S.C. and commonly referred to as Section 1983, governs claims for violation of federal civil rights in involuntary treatment, and is triggered by the removal of particular rights. Section 1983 claims have been used against psychiatrists and may be raised in state court cases (*Jensen v. Lane County* 2000).

Most states have additional state laws concerning involuntary treatment in a hospital setting (e.g., the Lanterman–Petris–Short Act in California, California Welfare and Institutions Code Section 5000 et. seq.). Additionally, forms of assisted outpatient treatment like "Kendra's Law" (NY Ment. Hyg. §9.60) in New York and, more recently, "Laura's Law" (Cal. Welf. & Inst. Code §5345 et. seq.) in California that allow for a variety of mandated outpatient treatment options could generate legal challenges from patients.

Tarasoff duties

In many states, psychiatrists and other mental health professionals have duties specifically related to protecting or warning nonpatient individuals when specific viable threats are made against them. After 1974, a landmark pair of cases in California, *Tarasoff v. Regents of University of California I and II* (1974 and 1976), initiated a new area of potential legal liability. In those cases, Tatiana Tarasoff's murder by an individual who had made specific threats against her to her psychologist imposed upon psychiatrists and psychotherapists a new "duty to warn" potential victims of violence in the 1974 ruling and, replaced by a new "duty to protect" potential victims in the 1976 ruling, though a duty to warn could be one way to satisfy the duty to protect. California has since modified these requirements several times, most recently, returning to solely a "duty to protect."

In any event, both warning the individual and notifying police in California will satisfy the duty and will provide absolute immunity from a possible negligence claim in the event a patient carries out his or her threats (Weinstock et al. 2014). A recent review suggests that because of the wide range of state statutes and common law, mental health professionals are not always aware of the relevant duties in

their own states (Johnson et al. 2014). *Tarasoff*-type laws (in those states that have them), therefore, provide additional avenues for general and forensic psychiatrist liability.

In *People v. Clark* (1990, Section 6(b), 12), a California case, the court held that a forensic psychologist who disclosed statements (in a *Tarasoff*-type warning) that a defendant making threats to kill individuals was at worst harmless error. The court reasoned that the forensic mental health evaluator's duty as a "psychotherapist" was properly applied under *Tarasoff* as to "avert danger to others." That case involved an evaluation of a defendant who had murdered the husband of a former therapist and severely injured his former therapist who had previously ended therapy. The defendant wanted to "show her how much she had hurt him, and decided to do so by causing her to suffer similar emotional pain" by killing her husband. He later told a forensic psychologist retained by defense counsel that he had thoughts of hiring someone to kill his former therapist's brother and his ex-wife's employer. The psychologist applied a *Tarasoff* warning, the contents of which were admitted into the case at trial. The court mentions but does not elaborate specifically upon waiver of the attorney–client privilege in the case. On appeal, the court contends that even if admission of the contents of the *Tarasoff* warning was done in error it was "not prejudicial" and "Defendant's statements to Dr. Weinberger were a minor aspect of the overwhelming evidence of aggravating factors reflected in the circumstances of the crime itself."

In a more recent California case, *Elijah W. v. Superior Court* (2013), the Court of Appeals held that a forensic evaluation could be accomplished by a forensic psychologist who would "respect lawyer–client privilege" and would "not report client information concerning child abuse/neglect or a so-called *Tarasoff* threat to authorities." At issue in the case was the choice of attorney to hire a psychologist who would waive the requirements of mandated reporting and notify the attorney alone of any reports of abuse or threats made against an identifiable victim. The court held that "when a psychotherapist is appointed … to assist defense counsel, he or she is obligated to maintain the confidentiality of the client's communications not only by the psychotherapist–patient privilege but also by the lawyer–client privilege."

COMPLAINTS TO MEDICAL BOARDS AND PROFESSIONAL ASSOCIATIONS

General psychiatrists have an above average rate of claims filed against them to state medical boards (Reich and Schatzberg 2014). As well, patients generally have fewer barriers to filing claims to state medical boards than to courts of law. All U.S. members of AAPL are required to be members of either the American Psychiatric Association (APA) or the American Academy of Child and Adolescent Psychiatrists (AACAP).

If a complaint is filed with AAPL against a forensic psychiatrist for violations of ethical codes, the complaint is forwarded to either the local APA branch for possible censure or to AACAP who generally refers such cases to state medical boards. AACAP has no enforcement mechanism (Binder 2002).

Additionally, courts have allowed associations to discipline their members. The court in *Budwin v. American Psychological Association* (1994) held that witness immunity did not protect a forensic psychologist in a board-related action. In a pair of cases from the Seventh Circuit, the court held that appellant physicians could be suspended from their respective medical associations for violations of their ethical codes specifically relevant to expert witness testimony they provided (*Austin v. American Association of Neurological Surgeons* 2001; *Bradner v. American Academy of Orthopaedic Surgeons* 2014).

LEGAL IMMUNITY

Witness immunity

Witness immunity is a common-law protection at issue in a landmark case by the Supreme Court in 1983, which has often been cited in cases involving forensic psychiatrists. Witness immunity offers protections for statements made in performing witness testimony. The Supreme Court in *Briscoe v. Lahue* (1983) held that witness immunity applied to government officials. Its reasoning was twofold: first, witnesses may be reluctant to testify if they fear a retaliatory lawsuit by an aggrieved party and, second, they may be inclined to distort their testimony in fear of a retaliatory suit. In that case, a police officer testified about the likelihood a defendant's fingerprints matched those found at a crime scene. The officer testified to a higher likelihood than other organizations, including the FBI. The defendant filed a civil claim against the witness officer, which was dismissed, and the matter was appealed all the way up to the Supreme Court. The Court cited common law and the intent of Section 1983 in support of its ruling, suggesting that witness immunity served the public interest.

In *Dalton v. Miller* (1999), the Colorado Supreme Court held that quasi-judicial immunity (discussed below) did not apply in the facts of that case. An insurance company hired a psychologist to determine whether they should continue to insure the plaintiff. The court held that quasi-judicial immunity did not apply because the examiner was not court appointed but was hired by one side of a dispute. However, the doctrine of witness immunity applied to both video-taped deposition testimony to be used at trial as well as a written report for trial. In this case, the court remanded to the lower court for a determination of whether the exam itself caused harm for which witness immunity did not apply (citing *Greenberg v. Perkins*).

In *Murphy v. A.A. Mathews* (1992), the Missouri Supreme Court held that an accounting firm hired by one party for valuation of a claim was not allowed witness immunity as a professional firm that had agreed to provide litigation-related services for compensation and that the professional

firm was negligent in providing those services. The Court differentiated the facts of this case from *Briscoe v. LaHue* for three reasons: (1) that the claims were "outside the realm of defamation," (2) it did "not involve an adverse witness," and (3) the claim was "limited to litigation support services, not testimony." Potentially the reasoning in this case could apply to psychiatric expert witnesses.

Additionally, the court cited *James v. Brown*, a 1982 Texas Supreme Court case involving psychiatrists who testified that a patient was incompetent, as persuasive. The Texas Supreme Court in that case rejected blanket witness immunity for the psychiatrists, but noted that their communications to the court, regardless of how negligently made, could not serve as the basis for a defamation action. That court did leave open "other remedies at law" including "negligent misdiagnosis–medical malpractice."

Judicial and quasi-judicial immunity

Judicial immunity provides protections for state actors, barring civil actions against them in judicial proceedings. *Budwin v. American Psychological Association* (1994) describes quasi-judicial immunity as a doctrine that "bars civil actions against judges for acts performed in the exercise of their judicial functions and… applies to all judicial determinations… no matter how erroneous or even malicious or corrupt they may be… and has been extended to neutral third parties including psychologists." In that case involving child custody, a psychologist made false representations about performing specific play therapy with a child that the psychologist had not performed. Notably, the court ruled that quasi-judicial immunity did not prevent the American Psychological Association from disciplining the psychologist.

In California, *Silberg v. Anderson* (1990) laid out a test for "privilege for publication." They must be communications made in a judicial or quasi-judicial proceeding, by litigants or other participants authorized by law, to achieve the objects of the litigation and that have some connection or logical relation to the action. The case involved a divorce proceeding in which an attorney hired a "neutral" third-party psychologist who interviewed each member of a family. The father was cast in a negative light, and ultimately he was not pleased with the outcome of the proceedings. He alleged that the psychologist had a prior relationship to the mother and made claims against both his former spouse's attorney and his attorney for breach of contract, negligence, and "intentional tort." The Court said that quasi-judicial immunity did not apply to activities outside of court if the expert was hired by one of the parties to the case. However, if the expert was hired by the court, quasi-judicial immunity would apply.

Also in California, the California appellate court in 2008 decided *Lambert v. Carneghi* (2008) which held that the "litigation privilege" did not apply to an expert witness being employed by one party. In the case, a home fire completely destroyed Lambert's home which was covered by fire insurance. The parties could not agree on a valuation of the home, so according to the California Insurance Code, one appraiser was hired by each party and a retired judge as an umpire. The Lamberts claimed that the umpire was not educated appropriately and "demonstrated a fundamental misunderstanding" of replacement costs, and that their appraiser failed to clarify the meaning of the term "replacement cost." They filed suit against both appraisers and on appeal the court upheld the demurrer to the appraiser hired by the insurance company but that the demurrer granted to their own expert was in error. The court held that privilege bars suit against opposing experts and experts hired jointly but not experts hired by themselves. The court discounted arguments that the application of privilege would promote truthful testimony and would promote finality of judgments, and that fewer experts would be willing to become involved if they could later be sued by the part who retained them. Instead they held that the litigation privilege does not apply to prevent a party from suing his or her own expert witness, even if that suit is based upon the expert's testimony. The Supreme Court of California denied cert and declined to hear the case. Most disturbing in this case is that the court gave no credence to the ethical requirement for experts in areas like forensic psychiatry to strive to reach an objective opinion (AAPL Ethics Guidelines 2005), even if that did not help the retaining attorney win his case. Although this case did not involve forensic psychiatrists, it would be quite disturbing if this reasoning was extended to forensic psychiatry. In essence it could find forensic psychiatrists liable to suits from retaining attorneys for giving honest opinions that do not help attorneys with their cases, or for giving honest answers in cross-examination. It could pressure forensic psychiatrists into being "hired guns" to help attorneys win cases out of fear of being sued by a retaining attorney.

In *Politi v. Tyler* (2000), a Vermont case, a psychologist was not granted quasi-judicial immunity. The specific facts of the case suggested that a forensic expert was hired by the parties themselves and was not court appointed. The court cited the contractual language and payment structure for distinguishing the psychologists' claims of being court appointed. Of note, a dissenting opinion viewed the facts differently and believed that the trial court did, in fact, order a forensic evaluation. The dissent cited a hearing to "determine who pays the cost of such evaluation and may order a party, the parties, or the court or some combination thereof to pay" and ultimately in a hand written note "hearing held. Forensic evaluation will be done… Counsel to let us know within a week who to engage for a forensic evaluation." Despite claims that judicial immunity is decided "as a matter of law" specific facts of this case led the Court to conclude that this was not a "court ordered" evaluation and, thus, quasi-judicial immunity did not apply. The court held that witness immunity did apply for statements "made on the witness stand" but not for the malpractice claim based on actions "in conducting a forensic evaluation and preparing a report."

SUMMARY

Overall, legal claims made against psychiatrists are less frequent than in other medical specialties and lower still for forensic psychiatrists. The above outlines potential avenues for lawsuits against forensic psychiatrists. Medical board claims, though, are filed against psychiatrists at a higher rate than other specialties, and no specific data are available for rates of claims against forensic psychiatrists in their forensic practice. Additional legal protections may apply to forensic psychiatrists in their forensic practice based on limited physician–patient relationships. The forensic psychiatrist should be aware of increasing exploration into lawsuits against IME practitioners based on the relationship that could develop in a forensic evaluation. Forensic psychiatrists might consider frank discussions and even providing documentation to their examinees that explicitly delineates the relationship of their forensic clients (Weinstock and Garrick 1995). Multiple factors are considered by courts in determining when a physician–patient relationship exists.

Additionally, some state licensing boards call forensic psychiatric practice the practice of medicine and discipline psychiatrists accordingly, even if out of state. The AMA says there is a limited doctor–patient relationship in performing IME evaluations.

Binder provides a list of guidelines for risk management techniques, which we add (with bracketed modification to reflect current recording practices) here as helpful, including the following (Binder 2002):

1. Not specifying a likely result or opinion and/or advertising how your services will achieve that result
2. Arranging fees and expenses, including retainers, at the outset of consultation
3. Maintaining strict records, including [audio and/or video recording]
4. Conducting interviews when appropriate
5. Keeping the attorney informed of your opinion as it develops
6. Not overstating your opinions
7. Not taking cases beyond your ability and expertise
8. Preserving the attorney's and client's confidence, as specified in the legal proceedings in which you are involved

As in all contexts involving possible liability, forensic psychiatrists should be aware of and clearly demarcate the exact parameters of their employment, and should seek legal counsel should legal liability become an issue.

The death penalty

MICHAEL L. PERLIN AND ALISON J. LYNCH

INTRODUCTION

There have been three generations of death penalty law in the United States. The first, from the founding of the nation until the Supreme Court's 1972 decision in *Furman v. Georgia*, striking down all then-existing death penalty laws as violative of the Eighth Amendment's ban on cruel and unusual punishment, was marked by standardless imposition of the penalty with little thought given to the individual circumstances of the crime or the criminal. The second, the four years between the Court's decision in *Furman* and its 1976 decision in *Gregg v. Georgia*, finding constitutional the penalty as redrafted in certain states, was marked by a flurry of activity in state legislatures. The third, ongoing and encompassing all death penalty developments since *Gregg*, has been marked by a constant tinkering with the *Gregg* standards, and the development of a cluster of sub-issues to which the Court has returned again and again in its efforts to determine whether state policies meet constitutional muster. Among this cluster are several areas of specific and important interest to forensic psychiatrists, and it is these areas on which we focus in this chapter:

- Predictions of dangerousness
- The role of mitigation evidence
- Competency to be executed, as that concept applies to
  - Juveniles
  - Persons with intellectual disabilities
  - Persons with mental illness

On the related question of the right of defendants who are facing the death penalty to oppose involuntary medication to render them competent to be executed, see Chapter 57.

FUTURE DANGEROUSNESS

In an effort to ensure the "worst of the worst" receive death sentences, many jurisdictions encourage jurors to consider the danger a defendant will pose to society in the future by including "future dangerousness" as an aggravating factor (Vann 2011). The inclusion of this factor, however, assumes the existence of three important facts-not-in-evidence: that mental health professionals can accurately predict dangerousness, that defense counsel can effectively cross-examine state experts on this issue, and that jurors can competently assess this sort of testimony. A review of the case law and the professional literature makes it clear that none of these questions can be answered affirmatively.

On mental health professionals' predictions of dangerousness

In *Jurek v. Texas,* the Supreme Court upheld the constitutionality of a state statutory scheme requiring, inter alia, that the jury determine, beyond a reasonable doubt, whether there was a "probability that the defendant would commit criminal acts of violence that would constitute a continuing threat to society" (Tex. Crim. Proc. Art. §37.071(2)(b)(1), 1976). On this issue, the controlling plurality opinion established its guidelines as to such a "dangerousness" finding:

> What is essential is that the jury has before it all possible relevant information about the individual defendant whose fate it must determine. Texas law clearly assures that all such evidence will be adduced. (Jurek 1976, 274)

The decision in *Jurek* was immediately criticized as "appalling" (Black 1976, 8), and as "difficult to reconcile" with the Court's recognition in *Gregg v. Georgia* that "the concept of human dignity underlying the Eighth Amendment demands a principled application of the death penalty" (Harvard Law Review 1976, 71). This aspect of the opinion was specifically seen as flawed by vagueness and prejudicially misleading to the defendant (Scofield 1980; Green 1984). *Jurek* was partially overruled by *Abdul-Kabir v. Quarterman* (2007), but nothing in that decision has had much of an impact on the questions under consideration in this chapter (Perlin 2013, 20).

The significance of barefoot

Although psychiatric testimony was not at the core of the *Jurek* opinion, that issue emerged clearly and explicitly several terms later in the severely criticized opinion of *Barefoot v. Estelle*. After Barefoot was convicted of murdering a Texas police officer, two psychiatrists (who had never examined the defendant) testified in response to hypothetical questions at the penalty phase, stating that the defendant "would probably commit further acts of violence and represent a continuing threat to society" (*Barefoot v. Estelle* 1983, 884). The jury accepted this testimony and imposed the death penalty.

In affirming a subsequent opinion denying the defendant's application for a writ of habeas corpus, the Supreme Court summarized the defendant's claim on the psychiatric issue:

> First, it is urged that psychiatrists, individually and as a group, are incompetent to predict with an acceptable degree of reliability that a particular criminal will commit other crimes in the future, and so represent a danger to the community. Second, it is said that in any event, psychiatrists should not be permitted to testify about future dangerousness in response to hypothetical questions and without having examined the defendant personally. Third, it is argued that in the particular circumstances in this case the testimony of the psychiatrists was so unreliable that the sentence should be set aside. (*Barefoot v. Estelle* 1983, 896)

The Court first rejected the argument that psychiatrists could not reliably predict future dangerousness in this context, noting that it made "little sense" to exclude *only* psychiatrists from the "entire universe of persons who might have an opinion on this issue" (*Barefoot v. Estelle* 1983, 896), and that the defendant's argument would also "call into question those other contexts in which predictions of future behavior are constantly made" (*Barefoot v. Estelle* 1983, 898). In the course of this argument, the Court rejected the views presented by the American Psychiatric Association as *amicus* that (1) such testimony was invalid due to "fundamentally low reliability" and (2) long-term predictions of future dangerousness were essentially lay determinations that should be based on "predictive statistical or actuarial information that is fundamentally nonmedical in nature" (Brief Amicus Curiae 1983, 14).

Justice Blackmun dissented (for himself, and Justices Brennan and Marshall), rejecting the Court's views on the psychiatric issue:

> In a capital case, the specious testimony of a psychiatrist, colored in the eyes of an impressionable untouchability of a medical specialist's words, equates with death itself. (*Barefoot v. Estelle* 1983, 916)

Relying on the American Psychiatric Association's *amicus* brief, he concluded that such "baseless" testimony cannot be reconciled with the Constitution's "paramount concern for reliability in capital sentencing" (*Barefoot v. Estelle* 1983, 917).

Role of jurors

The majority assumed that jurors will be able to adequately assess this testimony. It noted pointedly:

> Petitioner's entire argument, as well as that of Justice Blackmun's dissent, is founded on the premise that a jury will not be able to separate the wheat from the chaff. We do not share in this low evaluation of the adversary process. (*Barefoot v. Estelle* 1983, 901 n. 7)

The uncontroverted facts paint a dismal picture and show how misguided the majority was. Violence risk assessment errors continue at capital sentencing (Cunningham and Reidy 1999; Tanner 2005). At the best, future dangerousness determinations are "wildly speculative" (Berry 2010, 907). One study concluded jurors making a prediction of future violence—the factor that is the jurors' "overriding concern" (Ramana 2011, 369) or "predominant consideration" (Blume et al. 2001, 404)—were wrong 97% of the time, showing only "chance-level" performance of capital juries in predicting future dangerousness (Vann 2011, 1273 n. 141).

Barefoot is especially troubling because research shows future dangerousness plays a part in almost all jury determinations to impose a death sentence (Vann 2011, 1274 n. 141). By way of example, between 1995 and 2006, "future violence was alleged as a non-statutory aggravating factor in [77]% of the federal capital prosecutions" and a "death [sentence] occurred in over 80% of the federal cases where the jury found that future prison violence was likely," because such predictions are "alarmingly unreliable" (Shapiro 2008, 147).

MITIGATION

Contemporaneous death penalty statutes require findings of what are called "mitigating" and "aggravating" factors. This is ostensibly done to ensure that the death penalty is reserved for only the vilest of crimes and the worst offender—ones for which there is no reasonable excuse or justification (Mandery 2003; Smith 2012). Among the mitigators is evidence of a showing that the defendant was under the influence of extreme mental or emotional disturbance or that the capacity of the defendant to appreciate the criminality of his conduct or to conform his conduct to the requirements of law was substantially impaired.

The verdict must be death if the jury unanimously finds at least one aggravating circumstance and no mitigating circumstance or if the jury unanimously finds one or more aggravating circumstances that outweigh any mitigating circumstances (e.g., 42 Pa. C.S.A. §9711(c)(4),

2010). The verdict must be a sentence of life imprisonment in all other cases.

In determining the degree to which mitigation based on mental disorder is proper, these are factors that must be considered in each case:

1. Whether the offender's suffering evidences expiation or inspires compassion
2. Whether the offender's cognitive and/or volitional impairment at the time he or she committed the crime affected his or her responsibility for his or her actions, and thereby diminished society's need for revenge
3. Whether the offender, subjectively analyzed, was less affected than the mentally normal offender by the deterrent threat of capital punishment at the time he or she committed the crime
4. Whether the exemplary value of capitally punishing the offender, as objectively perceived by reasonable persons, would be attenuated by the difficulty those persons would have identifying with the executed offender (Liebman and Shepard 1978, 818).

In *Lockett v. Ohio*, the Supreme Court substantially widened the scope of mitigating evidence allowed at the penalty phase of a capital case (*Lockett v. Ohio* 1978, 604). Four years later, the Court expanded on this rule in *Eddings v. Oklahoma*, holding that the sentencing authority must consider any and all relevant mitigating evidence (*Eddings v. Oklahoma* 1982, 114). There, the Court concluded that the sentencer must consider all mitigating evidence and then weigh it against the aggravating circumstances (*Eddings v. Oklahoma* 1982, 113). Read together, *Lockett* and *Eddings* thus "require the courts to admit into evidence, and to consider, *any* claim raised by the defendant in mitigation" (Showalter and Bonnie 1984, 161). Then, in *Penry v. Lynaugh*, the Supreme Court held that evidence as to the defendant's mental retardation was relevant to his culpability and that without such information jurors could not express their "reasoned moral response" in determining the appropriateness of the death penalty. There, the court found that assessment of the defendant's retardation would aid the jurors in determining whether the commission of the crime was "deliberate" (*Penry v. Lynaugh* 1989, 321). Also, in attempting to grapple with questions of future dangerousness or of the presence of provocation (both questions mandatory under the Texas state sentencing scheme), jurors were required to have a "vehicle" to consider whether the defendant's background and childhood should have mitigated the penalty imposed (*Penry v. Lynaugh* 1989, 322). Without such testimony, the jury could not appropriately express its "reasoned moral response" on the evidence in question (*Penry v. Lynaugh* 1989, 328).

Subsequent decisions have reconfirmed the Court's commitment to this approach. By way of example, in *Porter v. McCollum*, the Supreme Court reversed an Eleventh Circuit decision that had reversed a grant of habeas corpus, in a case in which the state court had not considered expert testimony for purposes of nonstatutory mitigation and "unreasonably discounted the evidence of [the defendant's] childhood abuse and military service" (*Porter* 2009, 455).

IMPOSITION OF DEATH PENALTY ON SPECIAL POPULATIONS

Introduction

The issues involved in psychiatric participation in capital punishment decision making raise a series of intractable (Ward 1986, 100) operational problems for mental health professionals in cases involving juveniles and defendants with mental disabilities: the responsibility of psychiatrists to construe appropriately the key terms in operative statutes, assessment of the appropriate standard of proof; reliability of diagnoses; and possibility of regression between evaluation and execution (Radelet and Barnard 1986, 43). They also raise core ethical problems that have not yet been resolved.

Juveniles

In 2005, the Supreme Court decided in *Roper v. Simmons* that the state cannot execute an individual who commits a crime before the age of 18. The Court relied on objective factors, including the "evolving standards of decency" in the United States. Most significantly, it examined scientific evidence pertaining to the juvenile brain. The justices took into account factors such as "juveniles' immature judgment, susceptibility to negative peer influences, and transitory personality development" (Feld 2008) in finding that these age-appropriate developmental markers diminished their criminal responsibility. Therefore, the Court found, juveniles did not deserve the most serious sentence that can be imposed on adults.

Although *Roper* was praised as a decision based on reason and objective factors, the written decision of the Court provides little social science evidence as support; however, many of the amicus briefs written in support of abolishing the juvenile death penalty provide ample references to developmental psychology and neuroscience that illustrate the differences in juvenile brains (Feld 2008). Additionally, the decision still allowed for the imposition of life without parole, which social scientists and researchers denounced (Flynn 2008). This decision left many questioning whether it went far enough in demonstrating the law's understanding of the developmental differences of juveniles (Flynn 2008).

Defendants with mental illness: *Ford v. Wainwright*

Eight years after Alvin Ford's murder conviction, he developed delusions and hallucinations, and his letters revealed "an increasingly pervasive delusion that he had become the target of a complex conspiracy, involving the [Ku Klux] Klan and … others, designed to force him to commit suicide"

(*Ford v. Wainwright* 1986, 400). His treating psychiatrist concluded that the defendant suffered from a "major mental disorder severe enough to substantially affect [defendant's] present ability to assist in the defense of his life" (*Ford v. Wainwright* 1986, 402). Ford's lawyer then invoked Florida procedures governing the determination of competency of an inmate sentenced to death, and, after brief meetings, three state-appointed psychiatrists all found him to have sufficient capacity to be executed under state law.

In the only portion of any of the four separate opinions in the *Ford* case to command a majority of the Court, Justice Marshall concluded that the Eighth Amendment did prohibit the imposition of the death penalty on an insane prisoner (*Ford v. Wainwright* 1986, 405). In coming to its determination, the Court must take into account objective evidence of contemporary values before determining whether a particular punishment comports with the fundamental human dignity that the Amendment protects (*Ford v. Wainwright*, 406, citing the plurality opinion in *Coker v. Georgia* 1977, 597).

On the question of what procedures were appropriate in such a case, the Court was sufficiently fragmented that no opinion commanded a majority. In a four-Justice opinion, Justice Marshall concluded that a *de novo* evidentiary hearing on Ford's sanity was required, unless the state-court trier of fact has after a full hearing reliably found the relevant facts. In cases such as the one before the Court where fact-finding procedures must aspire to a heightened standard of reliability, the ascertainment of a prisoner's sanity as a lawful predicate to execution calls for no less stringent standards than those demanded in any other aspect of a capital proceeding, a standard particularly demanding in light of the reality that the present state of the mental sciences is at best a hazardous guess, however conscientious (*Ford v. Wainwright* 1986, 412).

The opinion left it to the state to develop appropriate procedures to enforce the constitutional restriction upon its execution of sentences, noting that it was not suggesting that only a full trial on the issue of sanity will suffice to protect the federal interests (*Ford v. Wainwright* 1986, 416).

The dissenting justices reasoned that the Eighth Amendment did not create a substantive right not to be executed while insane (e.g., *Ford v. Wainwright* 1986, 427 [O'Connor, J., concurring in part and dissenting in part]) and that Florida's procedures were "fully consistent with the common law heritage and current practice on which the Court purports to rely" [*Ford v. Wainwright* 1986, 431, Rehnquist, J., dissenting]), and that the majority decision might lead to the advancement of entirely spurious claims of insanity.

IN THE AFTERMATH OF *FORD*: THE MEANING OF *PANETTI*

The Supreme Court returned to this question two decades later in the case of Scott Panetti. Panetti, who had been convicted of capital murder in the slayings of his estranged wife's parents, had been hospitalized numerous times for serious psychiatric disorders (*Panetti v. Quarterman* 2007, 936) Notwithstanding his "bizarre," "scary," and "trance-like" behavior, he was found competent to stand trial and competent to waive counsel. He was convicted despite his defense of insanity and sentenced to death. After his direct appeals and initial petition of habeas corpus were rejected, Panetti filed a subsequent habeas writ petition, alleging that he did not understand the reasons for his pending execution (*Panetti v. Quarterman* 2007, 935). This petition was rejected, the court concluding that the test for competency to be executed "requires the petitioner know no more than the fact of his impending execution and the factual predicate for the execution" (*Panetti v. Quarterman* 2007, 942). The Fifth Circuit affirmed—finding that the fact-finding procedures on which the trial court relied were "not adequate for reaching reasonably correct results" or, at a minimum, resulted in a process that appeared to be "seriously inadequate for the ascertainment of the truth" (*Panetti v. Quarterman* 2007, 954), and the Supreme Court granted certiorari.

The Court reversed in a 5–4 decision, and in the course of its opinion, significantly elaborated on its *Ford* opinion in two dimensions: as to the procedures that are to be afforded to a defendant seeking to assert a *Ford* claim, and as to the substance of the *Ford* standard.

On the first matter, it found error below in the trial court's failure to provide the defendant an adequate opportunity to submit expert evidence in response to the report filed by the court-appointed experts, thus depriving him of his "constitutionally adequate opportunity to be heard" (*Panetti v. Quarterman* 2007, 950). On the second, it carefully elaborated on and clarified the *Ford* decision. It reviewed the testimony that demonstrated the defendant's "fixed delusion" system, and quoted with approval expert testimony that had pointed out that "an unmedicated individual suffering from schizophrenia can 'at times' hold an ordinary conversation and that 'it depends [whether the discussion concerns the individual's] fixed delusional system'" (*Panetti v. Quarterman* 2007, 955). Here, it rejected the Court of Appeals' interpretation of the *Ford* standard.

This narrow test, the Supreme Court concluded, unconstitutionally foreclosed the defendant from establishing incompetency by the means that Panetti sought to employ in the case at bar: by making a showing that his mental illness "obstruct[ed] a rational understanding of the State's reason for his execution" (*Panetti v. Quarterman* 2007, 956) In this case, the Court found, the Fifth Circuit improperly treated a prisoner's delusional belief system "as irrelevant if the prisoner knows that the State has identified his crimes as the reason for his execution." Nowhere, the Court continued, did *Ford* indicate that "delusions are irrelevant to 'comprehen[sion]' or 'aware [ness]' if they so impair the prisoner's concept of reality that he cannot reach a rational understanding of the reason for the execution." If anything, the court continued, "the *Ford* majority suggests the opposite" (*Panetti v. Quarterman* 2007, 958). There was no support in *Ford* ("or anywhere else"), the Court added, for

the proposition that "a prisoner is automatically foreclosed from demonstrating incompetency once a court has found he can identify the stated reason for his execution" (*Panetti v. Quarterman* 2007, 959).

Among the questions to be explored in greater depth on remand was "the extent to which severe delusions may render a subject's perception of reality so distorted that he should be deemed incompetent," citing here to an aspect of the amicus brief by the American Psychological Association that had discussed ways in which mental health experts can inform competency determinations (*Panetti v. Quarterman* 2007, 962).

Defendants with intellectual disabilities

ATKINS V. VIRGINIA

[Author's note: For a discussion of pre-*Atkins* law, see Perlin and Cucolo 2016, §12-4.2.1, at 17-81 to 17-85.]

Atkins had been convicted of capital murder. In the penalty phase, the defense called a forensic psychologist, who testified that Atkins was "mildly mentally retarded" (with an IQ of 59) (*Atkins v. Virginia* 2002, p. 309). The jury convicted Atkins and sentenced him to death; after that sentence was set aside (for unrelated reasons), the same witness testified at the rehearing. At this time, the state called its own witness in rebuttal, who testified that the defendant was not retarded, that he was "of average intelligence, at least" (*Atkins v. Virginia* 2002, 309). The jury again sentenced Atkins to death, and this sentence was affirmed by the Virginia Supreme Court (*Atkins v. Virginia* 2002, 310).

In weighing the case, the Supreme Court pointed out that its inquiry should be guided by "objective factors," and that, in assessing these factors, the "clearest and most reliable objective evidence of contemporary values is the legislation enacted by the country's legislatures" (*Atkins v. Virginia* 2002, 312). As part of this inquiry, it noted the significant changes since it decided *Penry* in 1989 when only two states banned the execution of persons with mental retardation; in the intervening 13 years, at least another 16 (and the federal government) enacted similar laws (*Atkins v. Virginia* 2002, 314–315).

Further, the Court perceived that this consensus "unquestionably reflects widespread judgment about the relative culpability of mentally retarded offenders and the relationship between mental retardation and the penological purposes served by the death penalty" (*Atkins v. Virginia* 2002, 317).

Mental retardation, the Court found, involves "not only subaverage intellectual functioning, but also significant limitations in adaptive skills such as communication, self-care, and self-direction that became manifest before age 18" (*Atkins v. Virginia* 2002, 317). It continued in the same vein:

> Mentally retarded persons frequently know the difference between right and wrong and are competent to stand trial. Because of their impairments, however, by definition they have diminished capacities to understand and process information, to communicate, to abstract from mistakes and learn from experience, to engage in logical reasoning, to control impulses, and to understand the reactions of others. There is no evidence that they are more likely to engage in criminal conduct than others, but there is abundant evidence that they often act on impulse rather than pursuant to a premeditated plan, and that in group settings they are followers rather than leaders. Their deficiencies do not warrant an exemption from criminal sanctions, but they do diminish their personal culpability. (*Atkins v. Virginia* 2002, 318)

In light of these deficiencies, the Court found that its death penalty jurisprudence provided two reasons "consistent with the legislative consensus that the mentally retarded should be categorically excluded from execution" (*Atkins v. Virginia* 2002, 318):

> First, there is a serious question as to whether either justification that we have recognized as a basis for the death penalty applies to mentally retarded offenders. *Gregg v. Georgia* identified "retribution and deterrence of capital crimes by prospective offenders" as the social purposes served by the death penalty. Unless the imposition of the death penalty on a mentally retarded person "measurably contributes to one or both of these goals, it 'is nothing more than the purposeless and needless imposition of pain and suffering,' and hence an unconstitutional punishment." (*Atkins v. Virginia* 2002, 319)

The reduced capacity of mentally retarded offenders provided an additional justification for a categorical rule making such offenders ineligible for the death penalty. The Court went on to note that there was an "enhanced" risk of improperly imposed death penalty in cases involving defendants with mental retardation because of the possibility of false confessions, as well as "the lesser ability of mentally retarded defendants to make a persuasive showing of mitigation in the face of prosecutorial evidence of one or more aggravating factors" (*Atkins v. Virginia* 2002, 320). The Court also stressed several additional interrelated issues: the difficulties that persons with mental retardation may have in being able to give meaningful assistance to their counsel, their status as "typically poor witnesses," and the ways in which their demeanor "may create an unwarranted impression of lack of remorse for their crimes" (*Atkins v. Virginia* 2002, 321).

Here the Court acknowledged an important difficulty: "reliance on mental retardation as a mitigating factor

can be a two-edged sword that may enhance the likelihood that the aggravating factor of future dangerousness will be found by the jury," raising the specter that "mentally retarded defendants in the aggregate face a special risk of wrongful execution" (*Atkins v. Virginia* 2002, 321). Thus, the Court concluded, "Construing and applying the Eighth Amendment in the light of our 'evolving standards of decency,' we therefore conclude that such punishment is excessive and that the Constitution 'places a substantive restriction on the State's power to take the life' of a mentally retarded offender" (*Atkins v. Virginia* 2002, 321).

HALL V. FLORIDA

The Supreme Court's holding in *Atkins v. Virginia* was subsequently clarified, modified, and expanded in *Hall v. Florida*. *Hall* made it clear that inquiries into a defendant's intellectual disability (for purposes of determining whether he or she is potentially subject to the death penalty) cannot be limited to a bare numerical "reading" of an IQ score.

Under Florida law, if a defendant's IQ was 70 or under, he or she was deemed intellectually disabled; if, however, his or her IQ measured 71 or above, all further inquiries into intellectual disability—for purposes of determining whether *Atkins* would apply—were foreclosed (*Hall v. Florida* 2014, 1990). *Hall* declared this rule unconstitutional as it created an "unacceptable risk" that persons with intellectual disabilities would be executed (*Hall v. Florida* 2014, 1990).

Hall was sentenced to death. Later, because of an intervening Supreme Court decision that capital defendants must be permitted to present nonstatutory mitigating evidence in death penalty proceedings (*Hitchcock v. Dugger* 1987), he was resentenced. At this resentencing hearing, he presented "substantial and unchallenged evidence" of his intellectual disability (*Hall v. Florida* 2014, 1990). The jury resentenced him to death, and this recommendation was accepted by the sentencing court (*Hall v. Florida* 2014, 481–482).

Following the Supreme Court's decision in *Atkins*, Hall was unsuccessful in seeking the application of that case. On further appeal, in a 5–4 decision, per Justice Kennedy, the Court began by restating its rationale from *Atkins*: that "no legitimate penological purpose is served by executing a person with intellectual disabilities" (*Hall v. Florida* 2014, 1992, citing *Atkins*, pp. 317, 320). After returning to its *Atkins* language on the rationales of punishment, the Court added that the prohibition on such executions is required "to protect the integrity of the trial process" (*Hall v. Florida* 2014, 1993), noting that this population faces "'a special risk of wrongful execution'" because "they are more likely to give false confessions, are often poor witnesses, and are less able to give meaningful assistance to their counsel" (*Hall v. Florida* 2014, 1993). The question before the Court was thus how intellectual disability needed to be defined for purposes of executability.

Justice Kennedy began this section of the opinion by noting that it was proper to consult the "medical community's opinions" on this issue (*Hall v. Florida* 2014, 1993). He then returned to *Atkins,* pointing out that, in that decision, the Court noted that the medical community defined intellectual disability according to three criteria: "significantly subaverage intellectual functioning, deficits in adaptive functioning (the inability to learn basic skills and adjust behavior to changing circumstances), and onset of these deficits during the developmental period" (*Hall v. Florida* 2014, 1994, citing *Atkins*, p. 308 n. 3, and *amicus curiae* brief of the American Psychological Association). The first two of these criteria were central, he said, as they had "long been" the defining characteristic of intellectual disability (*Hall v. Florida* 2014, 11).

Because, under Florida law, the standard error of measurement (SEM) was ignored, and a bright-line rule that any person with an IQ measured over 70 was not intellectually disabled was created, thus barring the defendant from introducing any other evidence that would show that "his faculties are limited" (*Hall v. Florida* 2014, 1994), state sentencing courts cannot consider "even substantial and weighty evidence of intellectual disability as measured and made manifest by the defendant's failure or inability to adapt to his social and cultural environment, including medical histories, behavioral records, school tests and reports, and testimony regarding past behavior and family circumstances" (*Hall v. Florida* 2014, 1994). This is so even though the medical community accepts that all of this evidence can be probative of intellectual disability, including for individuals who have an IQ test score above 70 (*Hall v. Florida* 2014, 1994).

Thus, the Court concluded, Florida's rule disregarded "established medical practice" in two interrelated ways:

> It takes an IQ score as final and conclusive evidence of a defendant's intellectual capacity, when experts in the field would consider other evidence. It also relies on a purportedly scientific measurement of the defendant's abilities, his IQ score, while refusing to recognize that the score is, on its own terms, imprecise. (*Hall v. Florida* 2014, 1994)

This rule is contrary to all professional judgment, the Court found: "The professionals who design, administer, and interpret IQ tests have agreed, for years now, that IQ test scores should be read not as a single fixed number but as a range." The SEM reflects the reality that "an individual's intellectual functioning cannot be reduced to a single numerical score" (*Hall v. Florida* 2014, 1994). Were the states to have complete autonomy to define intellectual disability as they wished, "the Court's decision in *Atkins* could become a nullity, and the Eighth Amendment's protection of human dignity would not become a reality" (*Hall v. Florida* 2014, 1999).

Again, in declaring the Florida rule unconstitutional, the Court stressed that it was informed by the views of medical experts, whose opinions "inform … but [do] not control ultimate legal determinations," underscoring that neither Florida nor its supporting *amici* "point to a *single*

medical professional who supports this cutoff," and that Florida's rule "goes against unanimous professional consensus," noting again that "intellectual disability is a condition, not a number," and that it was not "sound to view a single factor as dispositive of a conjunctive and interrelated assessment" (*Hall v. Florida* 2014, 2000). Justice Alito dissented, critiquing the majority opinion as being based on "the views of *a small professional elite*" (*Hall v. Florida* 2014, 2005).

It is likely that *Hall* will clarify some of the confusion that has arisen in the 12 years since *Atkins* was decided as to who is to be considered "intellectually disabled" for purposes of death penalty eligibility. The majority opinion makes it crystal-clear that a "number only" IQ assessment violates the Eighth Amendment, and its opinion reflects a careful consideration of prevailing—and unanimous—professional wisdom.

In his recent blog post about *Hall*, John Parry—for many years editor-in-chief of the *Mental and Physical Disability Law Reporter*—comes to this thoughtful conclusion:

> First, the 5–4 majority opinion reprioritizes the relative importance of the two major rationales used to justify the ban on executing persons with intellectual disabilities established in *Atkins* … This shift in emphasis substantially increases the possibility that in the future, defendants with other types of severe mental disorders may be constitutionally protected from being executed. Second, even if "contemporary values" change and a majority of Americans come to believe that executing persons with intellectual disabilities should be permitted, *Hall* has embraced a persuasive independent constitutional basis for upholding *Atkins*. (Parry 2014)

SUMMARY

Death penalty jurisprudence remains in flux. The cases discussed in this chapter reveal a pattern on the Supreme Court's part that suggest that further tinkering with the issues discussed here—future dangerousness predictions, mitigation, execution competency—will continue in the future. It is essential that forensic psychiatrists understand the Court's rationales in these cases, and incorporate those understandings into their evaluations and testimony.

Competence assessments

JENNIFER L. PIEL, GREGORY B. LEONG, AND ROBERT WEINSTOCK

INTRODUCTION

Forensic psychiatrists are commonly asked to evaluate mental competency for a specific activity. The skills and knowledge needed for specific competencies are context dependent and specific to the function or activity being evaluated. Accordingly, someone may be competent for one purpose yet incompetent for another. Competence also can vary as a person's underlying condition changes, or circumstances occur that challenge a person's capabilities. The forensic psychiatrist is tasked with assessing whether the individual has the requisite threshold levels of mental abilities to perform the activity in question. This chapter explores the concept of competence assessment, generally. Several subsequent chapters focus on specific types of competence assessments.

STANDARDS

Psychiatrists assist the court by providing information about an evaluee's unique mental abilities and limitations. Courts often take the recommendation of the forensic evaluator, but the ultimate determination of competence requires social value judgments left to the court to determine. In this manner, mental health providers may use the term "capacity" to distinguish that competence is a legal determination. Capacity refers to whether an individual can do the things required of the legal competency in question (Drogin and Barrett 2010). As the terms "capacity" and "competency" are often used interchangeably in the law, so are both terms used in this chapter.

It is important for the forensic evaluator to understand the legally significant activity and the functional skills required for the activity. For some competencies, statutory criteria outline the threshold skills or requirements for a person to be competent for the specific activity. Case law may also establish jurisdictional requirements for a competency or give guidance to statutory language on the subject. By way of illustration, all 50 states have adopted standards that are consonant with *Dusky v. United States* (1960) for competence to stand trial evaluations (Mossman et al. 2007).

Forensic evaluators should familiarize themselves with any relevant statutes, cases, or administrative regulations in the jurisdiction of the evaluation. Where no standard is articulated in the law, forensic evaluators must familiarize themselves with the objectives and functional skills required of the activity. Professional commentary on the competence such as practice guidelines or scholarly articles may additionally be useful to evaluators in determining the requisite knowledge and skills for any particular competence assessment.

CONCEPTUAL MODELS FOR COMPETENCE ASSESSMENT

Grisso (1986, 2003) conceptualizes a model of key characteristics relevant for competence assessments: functional, contextual, causal, interactive, judgmental, and dispositional. Functional abilities relate to a person's specific knowledge, beliefs, or understanding necessary to accomplish a given task. Some authors have broken this down into discrete subcategories, such as cognitive functioning, psychiatric or emotional functioning, and everyday functioning (ABA/APA 2008). This is relevant because some capacities, such as the capacity to enter into a business contract, may focus primarily on cognitive skills. However, other capacities, such as end-of-life decisions, may require cognitive and emotional skills. By way of illustration, a person with Alzheimer's disease may have diminished cognitive skills but may be able to express long-standing values that underlie their decisions (Karel et al. 2007). An individual may lack capacity to consent to treatment or research, but nevertheless retain capacity to appoint a proxy decision maker, most commonly someone with whom the evaluee has had a close relationship for years (Kim et al. 2011).

In Grisso's model, the fact that there are so many types of competence assessments speaks to the role of context as an important variable. Assessments of a person's competence require information about the evaluee's ability to function

in a specific area. Causal inferences are useful to relate abilities or deficits to a specific cause and to make future prognostications. For example, if a person's Alzheimer's disorder is the basis for his or her incapacity to make a medical decision, the diagnosis provides useful information about the person's prognosis and likely symptoms and future abilities. An interactive characteristic focuses on the person's abilities to meet demands in interactions with others or demands posed by a specific situation. The judgment component concerns whether the evaluee's deficit skills warrant a finding of legal incompetence. Finally, disposition refers to the consequences to a person upon a determination of legal incompetence.

Appelbaum and Gutheil (2007) distinguish between standards for general and for specific competence. General competence questions are raised when it is believed that a person is unable to make decisions about a wide range of affairs. A finding of incompetence can lead to a person being placed on a guardianship or conservatorship. Specific competence refers to the ability to perform a specific function. A person may be competent to function in one area but not in another, because differing capacities and abilities may be required. Making this distinction itself can be an important contribution by a forensic psychiatrist consulting with general physicians and psychiatrists.

A person who is assessed as generally incompetent is considered so for all legal purposes—that is, a global incompetence. However, such a person may be *de facto* competent for a specific purpose, and this fact should be brought to the court's attention. For example, a person not competent to handle his or her money, or make decisions about psychotropic medication, may be competent to decide whether to have his or her leg amputated for medical reasons. People on guardianships in most jurisdictions generally are considered legally incompetent for all purposes. Conservatorships in some states are more limited than guardianships, and may be for incompetence in some specified general areas but not others. In cases of actual or *de facto* competence in a limited area for a person adjudicated as legally or *de jure* incompetent, the person's consent should be obtained in addition to that of a conservator or guardian if practical considerations preclude a court hearing. If a person improves and general competency is restored, courts should be petitioned to rescind the guardianship or conservatorship. This situation is similar to that of adolescents and children who may be legally incompetent because of immaturity for most purposes, solely because of their age. In fact, they may be able to make more competent decisions than many adults in some circumstances, despite being considered legally incompetent. However, unlike the disabled adult, the law may refuse to recognize a minor as competent for some purposes despite the reality or facts of a situation, probably because of the perception of immaturity of juveniles.

The sliding-scale model has been utilized for competence to give informed consent (Roth et al. 1977; Withers et al. 2008), and may be instructive for other types of competence assessments. Differing thresholds may depend on the factors in a specific case, such as the risks and benefits of a decision and the reasonableness of an evaluee's choice. A high threshold tends to be utilized for competency if a person is prepared to make an unreasonable choice or a choice with significant risks. Rather than using unreasonable outcome *per se* as a criterion, such differing thresholds suggest that a more stringent attempt should be made to search for a deficit in the ability to weigh relevant information if an evaluee's choices are too unreasonable or risky. A person's choice should at least be understandable in order to be competent, even though it may be unwise. Many irrational elements enter into decisions by normal competent individuals (Brock and Wartman 1990). Values inevitably enter into any determination of reasonableness, but varying thresholds are most consistent with commonsense approaches to this issue.

Although the sliding-scale concept has most commonly been utilized in civil competence assessments (such as medical decision making), it can also be applicable in the criminal area. Criteria for competence to stand trial can be interpreted in varying ways depending on the seriousness of the offense or the unreasonableness of the defendant's wishes regarding a trial (Buchanan 2006). A serious offense or complex legal case may require a greater degree of ability of a defendant to understand the charges against him or her and to provide assistance to his or her attorney. Depression must be seriously considered as making a defendant incompetent to stand trial in the case of serious felonies if it leads to a wish for a strategy to be found guilty and perhaps even a wish for the death penalty. A lower threshold is probably necessary to stand trial for less serious crimes. Sliding-scale criteria probably are frequently utilized but usually are not so conceptualized in the criminal area.

In recent years there has been increasing research on the neuroscience of decision making. With an aging population and more emphasis on decision-making skills in persons with mental illness, further study may provide new frameworks for looking at specific capacities. Stormoen et al. (2014), for example, identified that multiple factors are involved in medical decision making among persons with cognitive impairment, but assessment of verbal knowledge was the best predictor of competency for medical decision making. In their study, reading speed (consisting of ability to read rapidly and understand text) was the most predictive single measure of capacity to make medical decisions. Cáceda et al. (2014) looked at paradigms, such as the prisoner's dilemma and gamble theory, as additional means to inform decision-making patterns.

By their nature, many capacity assessments will reveal factors that support each side of a capacity assessment. The American Bar Association articulated a balancing-of-factors approach in the Model Rules of Professional Conduct (ABA 2009). It identified the evaluee's ability to articulate

reasoning toward a decision, variability of state of mind, ability to appreciate consequences of a decision, the fairness of a decision, and whether the decision is consistent with known preferences or values of the evaluee.

Value judgments of the evaluator are implicit in each of these models. For example, different evaluators may give differing value and weight to autonomy, beneficence, paternalism, civil liberties, and social protection. Values are involved in establishing the cut-off line for abilities, which divides competence from incompetence (Faden and Beauchamp 1986). An evaluee's choices at the end of life may be contrary to what the evaluator would choose for himself or herself, for instance, but the evaluator is tasked with assessing the evaluee's skills, values, and beliefs. Accordingly, values enter into priorities and into determinations of how people ought to live, what people ought to be able to do, what value to give patient welfare, and what value to give to an individual's choice and preferences.

Objectivity denotes an evaluator's independence from significant interference due to bias. Such bias can come from the evaluator in the form of personal value judgments or from contextual factors, such as having a preexisting relationship with the evaluee or referring source for the evaluation (Heilbrun et al. 2014, 78). Although bias is an inevitable part of competence assessments, the forensic evaluators should report honestly and strive toward objectivity (AAPL Ethics Guideline 2005) in applying the requisite legal standard.

Further, value judgments should be distinguished from professional opinions and scientific data. For example, many judges and juries believe that children should be raised by conventional parents. Even though there is no empirical justification for this opinion, it still could affect the outcome of a parental fitness (capacity) hearing. Biases of the forensic psychiatrist should not be misrepresented as scientific data with reasonable medical certainty. Efforts should be made to obtain data supporting any such belief with an ethical responsibility to strive for objectivity.

TYPES OF COMPETENCE ASSESSMENTS

As mentioned, there are many different types of specific competence with varying criteria distinct for the relevant area of functioning. Although most assessments are present-day evaluations, forensic evaluators should be mindful that they could be asked to perform retrospective evaluations (e.g., determining whether someone was competent when he or she executed a will) or prospective (e.g., in guardianship proceedings, whether the evaluee's disabilities are expected to limit their future decision making). As there are numerous situations in which a person's competence to perform an activity is questioned, an exhaustive list is not provided here. Table 12.1 provides an illustrative list of criminal and civil competencies.

Several of these specific areas and their criteria are discussed in other chapters of this book.

Table 12.1 Examples of criminal and civil competencies

Examples of criminal competencies	Examples of civil competencies
Stand trial	Parent
Enter plea	Informed consent for treatment/treatment refusals
Testify	Consent for voluntary hospitalization
Waive counsel	Care for oneself/guardianship
Be sentenced	Consent for research
Waive appeals	Enter a contract
Waive *Miranda* rights	Marry, engage in sexual relationship, divorce
Confess	Vote
Refuse insanity defense	Drive
Be executed	Testamentary capacity, handle financial affairs, make a gift
	Testimonial in civil case
	Professional competency

COMMON ERRORS IN COMPETENCE ASSESSMENTS

A number of scholars have written on the evaluation and format of reports for various competence assessments. Mossman et al. (2007), for example, provide a comprehensive guide to competence to stand trial evaluations that includes ethical and cultural considerations and practical information on the assessment, formulating the opinion, and the written report. Important also is recognizing common errors made by forensic evaluators in assessing competence. Identified here are several common errors in competence assessments.

Failure to answer the question

In contrast to general clinical psychiatric evaluations, forensic evaluators need to define and answer the specific question asked. In civil competence assessment, this can be challenging because the person requesting the evaluation may not recognize a distinction, for example, between global incompetence and incompetence to make a medical decision. A competency assessment should not be a clinical assessment. Instead, the competency assessment should be tailored to the requisite knowledge and skills necessary for the competency in question.

Equating diagnosis with incompetency

A psychiatric diagnosis is not synonymous with incompetence or impairment. Only the manner in which the mental disorder interferes with functioning in a specified context is relevant to an assessment of incompetence.

However, diagnoses that include a severity description may be determinative. The *Diagnostic and Statistical Manual of Mental Disorders* (*DSM-5*) Neurocognitive Disorders are illustrative, as they are divided into Major and Mild Neurocognitive Disorders based, at least in part, on levels of functioning. Accordingly, certain diagnoses, such as Major Neurocognitive Disorder, may carry more weight in explaining incompetence (Weinstock et al. 2015). The law specifies the legal criteria, which differ depending on the type of competence evaluated. Oftentimes, incompetence is legally required to be the result of mental disease or defect.

Overreliance on assessment instruments

Many psychological test instruments (often questionnaires) have been developed for specific competencies and are increasingly being used in competence assessments (Nicholson and Norwood 2000). These instruments can be useful to an evaluator by assisting the evaluator in recognizing and focusing on commonly identified skills or criteria for a given competency. Because assessment tools are not individualized to a person or situation, these instruments produce objectivity and reliability. However, on this same basis, an evaluator who relies too heavily on an assessment tool may miss what is essential in a specific case. Although assessment instruments are useful in supporting a formulation of an evaluee, they are best used as one aspect of the forensic assessment, in addition (for example) to an interview and review of collateral material.

BIAS

The biases of an examiner also can influence the interpretation of terms utilized in the legal criteria. The most honest and effective approach is to be open about the data and also the abilities evaluated, as well as to explain which legal criteria were used and how they were interpreted. A competence assessment should indicate what areas of functioning were evaluated, how they were evaluated, and what factors were considered relevant and why. Simple conclusory statements should be avoided as they can conceal hidden value judgments and can disguise such value judgments as psychiatric expertise. As mentioned above, it is the examiner's responsibility to take measures to minimize bias by striving toward an objective assessment and opinion.

Failure to consider evaluee effort, deception, and malingering

Given the legal context of many competence assessments, forensic evaluators performing this type of work should consider whether the evaluee is putting forth effort in responding to the evaluator's assessment. In cases when the evaluee does not answer questions, for example, the evaluator should consider whether this is volitional. The forensic evaluator should also consider whether the evaluee is distorting (exaggerating or minimizing) symptoms, or malingering, as a possible explanation for his or her presentation and impaired functioning. As with other types of forensic assessments, collateral information, psychological testing, and careful interview can minimize evaluator error.

Using technical language

Psychiatry as a field has numerous technical terms, from terms to describe symptoms to diagnoses to treatment modalities. These terms may not be understood by persons without specific training in mental health. It is useful for the forensic psychiatrist to use language that is reasonably understandable to the audience. This could include, for instance, other medical providers or evaluators, a judge, attorneys, and the parties to the legal case. Minimizing the use of technical language—or jargon—helps reduce misinterpretation by others (Fuhrmann and Zibbell 2012, 181).

Opinion without support

In opining on the competence raised, the forensic evaluator should address the specific knowledge and functional tasks of the particular evaluee and provide supporting evidence for the skills in question. As above, it is not uncommon for an evaluator to equate diagnosis with impairment. Basic conclusory statements should be avoided because they can conceal hidden value judgments and can disguise such value judgments as psychiatric expertise. A helpful expert opinion lays out the relevant functional abilities and comments on how an evaluee's mental condition affects the evaluee's requisite abilities. It is useful to specify all the reasoning and criteria so that areas of agreement and disagreement can be determined.

SUMMARY

Forensic psychiatrists are especially suited for assessing a person's mental status and its potential for interfering with a specific area of functioning. If general psychiatrists are asked to make such assessments, forensic psychiatrists can provide consultation to them. Although different models and assessment tools may be utilized by the evaluator, the key focus should be on whether the individual has the requisite functional knowledge and skills to perform the specific legal competence. Minor technical disagreements should be differentiated from psychiatric data pertinent to the legal criteria. It is important to be clear about the differing aspects of competence to most readily assist the court and prevent attorneys from obfuscating the many areas of reliable and valid noncontroversial data.

Psychological autopsy and postmortem toxicology in forensic psychiatry

ANDREW KIM, MACE BECKSON, ALAN WAYNE JONES, AND ALAN L. BERMAN

INTRODUCTION

The Centers for Disease Control and Prevention (CDC) defines "suicide" as "death caused by self-directed injurious behavior with any intent to die as a result of the behavior" (CDC 2014). This definition thus implicates the thoughts and behaviors of the decedent, which may be unclear from the evidence available to the medical examiner investigating an unwitnessed, nonnatural death. In these cases, the decedent's mental state, as well as underlying precipitants and risk factors, become matters of legal significance on which the opinion of a forensic expert is often sought.

In 1957, to address such matters, the Los Angeles County Coroner, Theodore Curphey, MD, contracted with Dr. Edwin Shneidman and his colleagues at the Los Angeles Suicide Prevention Center to provide behavioral science consultation with respect to manner of death determinations in "equivocal" cases, where it was unclear whether the death was intentionally self-inflicted (Botello et al. 2013). Shneidman devised a protocol, christened the "psychological autopsy," to help investigators "make a reasonable determination of what was in the mind of the decedent vis-à-vis his or her own death" (Shneidman 1994, 75). As one high-profile example, investigators employed Shneidman's protocol in examining Marilyn Monroe's death from a barbiturate overdose in 1962 and concluded it was the result of a "probable suicide" (Botello et al. 2013).

The psychological autopsy consists of a systematic retrospective investigation of the decedent's state of mind at the time of death to determine (to the highest degree of certainty possible) whether the decedent was suicidal and, if so, what distal and proximal risk factors contributed to that suicide risk. In the psychological autopsy, the subject of the investigation has died and is unavailable for personal examination. Therefore, proxy informants, in addition to contemporaneous documentation, provide important data regarding the decedent.

In coroner's death determinations, the psychological autopsy is sought to elucidate the "manner of death" (or "mode of death"). Manner of death is distinguished from "cause of death," which refers to the immediate, mechanistic factors that terminated life, e.g., blunt force trauma to the head, myocardial infarction, etc. In contrast, manner of death captures the broader circumstances, typically certified as "natural," "accidental," "suicide," or "homicide" (the so-called "NASH" categories). A case is deemed "equivocal" when uncertainty arises as to the applicable NASH category. Without further clarification, the manner is left "undetermined" by the medical examiner.

The psychological autopsy also investigates the "motive" and the "intent" associated with the suicide. "Motive" encompasses the decedent's internal calculus of the reasons and circumstances supporting a decision to die by suicide, taking into account the current and prospective stressors and resources (Scott et al. 2006). "Intent" has been defined as the aim or goal to end one's life, including the conscious awareness and expectancy that the method used will cause death (Berman 2005). Implicit in intent, "mental capacity" refers to the decedent's ability to arrive rationally at the decision to die by suicide, considering such factors as intoxication, cognitive impairment, reality testing, and "sanity" (Scott et al. 2006).

This chapter will discuss the psychological autopsy with respect to applications; methodologies and limitations; interpretation and integration of toxicological results; ethical considerations; admissibility in court; and practical considerations for providing testimony.

APPLICATIONS

From its origins in assisting the Coroner, applications of the psychological autopsy have since spread into the courtroom and beyond. In research settings, the psychological autopsy has helped expand the knowledge base for suicide risk factors and suicide prevention.

In litigation, the psychological autopsy may be utilized where the manner of death is relevant to criminal culpability or civil liability. In criminal cases involving suspected homicide, a psychological autopsy may support or refute a criminal defense that the decedent's death was self-inflicted, as opposed to the result of foul play (Ogloff and Otto 1993). It has also been used to establish criminal responsibility for a known suicide. In *Jackson v. State*, the victim was a 17-year-old girl who died by gunshot wound after years of abuse by her mother, who had forged the victim's birth certificate and forced her to work as a nude dancer (553 So. 2d 719 [Fla. 4th DCA 1989]). The criminal investigation established that the victim died by suicide, but a psychological autopsy was admitted into evidence against her mother to support charges of child abuse, procuring sexual performance by a child, and forgery (Harris 1990).

Litigation over the denial of life insurance benefits often involves psychological autopsies. Where the policy at issue contains a suicide exclusion clause, payment of benefits to beneficiaries is denied when a self-inflicted death occurs within a specified time period from the start of the policy. Though intended to protect insurers against subterfuge by a newly insured person, public sentiment and policy tend to favor the beneficiaries of life insurance policies so as not to compound the beneficiaries' loss with the denial of benefits (Schuman 1993). Accordingly, the insurance company has the burden of proving a death was a suicide, and it may obtain a psychological autopsy to meet this burden. Correspondingly, the intended beneficiaries may seek a psychological autopsy to bolster their claim that the decedent's death was not a suicide. In *Evans v. Provident Life Ins. Co.*, the Kansas Supreme Court affirmed the admission of a psychological autopsy report opining that an insured decedent was suicidal at the time of his death (815 P.2d 550 [Kan. 1991]).

Even where manner of death is not equivocal, civil cases may still invoke a psychological autopsy to obtain a cross-sectional assessment of a decedent's mental state and suicide risk prior to death. In malpractice actions against psychotherapists, a psychological autopsy may be proffered to opine on the foreseeability of a decedent's suicide and thereby show proximate causation. Parties may also seek a psychological autopsy in wrongful death litigation involving possible "suicide-by-cop," product liability claims, workers' compensation claims, and military benefits awards to surviving families.

In research settings, the purpose of the psychological autopsy is not to determine whether suicide occurred, but rather to understand why it occurs. It is a practical and widely used approach to studying distal, proximal, and contributory suicide risk factors, i.e., underlying and acute psychological and situational preconditions to suicide. Because of the statistical rarity of suicide, e.g., 20.6 males and 5.5 females per 100,000 U.S. population in 2012 (Drapeau and McIntosh 2014), longitudinal studies requiring large sample sizes would be impractical. However, the case-control study design provides an alternative approach by comparing known suicide cases to matched control samples, such as known accidental deaths. Psychological autopsy studies utilizing this design have elucidated several risk factors associated with suicide, such as history of substance use disorders, depressive disorders, and prior suicide attempt, thereby enhancing clinical suicide risk assessment and prevention measures, as well as informing policy (Yoshimasu et al. 2008).

METHODOLOGY

Since its inception, various protocols have been developed to establish a structure for the psychological autopsy (e.g., Ebert 1987; Snider et al. 2006; Knoll 2009). Common to these protocols is the targeted gathering of evidence, typically from review of available records (e.g., autopsy reports, postmortem toxicology reports, suicide notes, journals, correspondences, insurance policies, and wills, as well as psychiatric, medical, pharmacy, employment, military, legal, and academic records) and interviews of family survivors and acquaintances (i.e., knowledgeable observers). These approaches facilitate the systematic collection of psychological, psychiatric, medical, and social data, including first-person accounts of the decedent's developmental history, character, coping style, and last days of life, such that "conclusions can be drawn as to the intention of the decedent, therefore the decedent's role in effecting his/her own death" (Berman 2005, 365). However, no single approach has emerged as the standard protocol for the conduct of a psychological autopsy, and the selection, interpretation, and weighting of each source of evidence remain largely a matter of evaluator discretion, leading to inter-rater variability. This lack of a standardized protocol has raised concerns as to the psychological autopsy's reliability and validity (Pouliot and De Leo 2006).

One response to such concerns has been to create structured rating instruments addressing the range of factors to be considered in the psychological autopsy. The CDC developed the "Empirical Criteria for the Determination of Suicide" (ECDS) by selecting those factors that best correlated empirically with self-infliction and suicidal intention: autopsy evidence; toxicology; witness statements; investigatory evidence (e.g., police reports, scene photos); psychological evidence (e.g., observed behavior, personality, and lifestyle); evidence that decedent recognized high-potential lethality of means; recent and sudden change in decedent emotions; serious depression or mental disorder in decedent; indications of desire to die, anticipation of impending death, or expressions of farewell (e.g., verbally or via a suicide note); expressions of hopelessness; actual or threatened stressful events or losses; instability in immediate family; recent interpersonal conflicts; and history of poor physical health (Jobes et al. 1991). These factors are organized into a 16-item instrument, with each item categorized as evidence of self-infliction, intention, or both. If a case achieves a score of three or more on both the self-infliction and intention scales (indicating there were at least three factors evidencing self-infliction and at least three factors evidencing

intention), then it is deemed a suicide. A lower score on either scale is interpreted as an accidental death. The ECDS was subjected to a validation study that applied the protocol to a blinded set of cases that had previously been certified as suicide or accidental. The ECDS correctly identified 100% of the known suicides and 82.75% of the accidents (Jobes et al. 1991).

Despite its elegance, the use of the ECDS is not without qualifications. It was not intended to obviate the investigator's clinical decision making, and it excludes traditional suicide risk factors, such as previous suicide threats or attempts, measures to prevent rescue, rehearsal of suicidal behavior, and preparations for death (Jobes et al. 1991). Moreover, the ECDS does not calculate probabilistic suicide risk. Rather, it was designed to provide medical examiners with a standardized instrument to help distinguish a suicide death from an accidental death for purposes of improving the accuracy of epidemiological data. To this extent, the ECDS may be overly deterministic, especially for forensic settings where more is required than merely sorting suicides from accidental deaths. The ECDS scoring system may also come across as conclusory, such that in litigation settings, expert opinion relying on the instrument may invite exclusion where testimony on an ultimate issue is barred.

An alternative protocol was developed based on a survey of suicidologist–forensic experts who considered the following areas of inquiry to be essential: documentation/records; site of death; demographics; recent symptoms/behaviors; precipitants to death; psychiatric history; physical health; substance abuse; family history; firearm history; attachments/social supports; emotional reactivity; lifestyle/character; and access to care (Snider et al. 2006). The "Semi-Structured Interview for Psychological Autopsy" systematizes the survivor interview along four domains: precipitants/stressors; motivation; lethality; and intentionality (Werlang and Botega 2003).

Though these protocols do offer a conceptual structure for the collection of autopsy data, true standardization remains unrealized. Most conspicuously, no decision rules govern what type or amount of evidence is sufficient to rule in or rule out suicide as the manner of death. However, standardized data points and domains have been defined (Snider et al. 2006), affording some assurance of reliability. At any rate, the lack of standardization is not unique to psychological autopsies and is common to many protocols in the behavioral sciences, including the typical psychiatric interview. Provided the psychological autopsy focuses on the degree of suicide risk, as opposed to whether the death was actually a suicide, it avoids overstepping into an ultimate issue that is reserved for the finder of fact.

RESOLVING INCONSISTENCIES IN THE EVIDENCE

The psychological autopsy frequently involves consideration of inconsistent or contradictory evidence (indeed, ambiguity is likely what prompted the psychological autopsy to be conducted in the first place). In manner of death determinations, medical examiners have variable access to information typically found in coroner's investigator reports, police investigation reports, medical records, and pharmacy records. Through discovery, the forensic expert may have a much larger database than that previously available to the medical examiner. Despite, or perhaps because of, an increased access to sources, the forensic expert commonly confronts inconsistencies in the evidence that may or may not be resolvable. Where such inconsistencies cannot be reconciled, the expert witness may offer alternative opinions based on competing versions of the facts.

One potential source of inconsistencies is the survivor interview. A survivor's recollection of the circumstances surrounding the relevant death is fraught with inherent bias, both conscious and unconscious, which may arise out of the survivor's feelings of guilt, anger, or shame, or out of personal interest in the outcome of the psychological autopsy. However, survivors provide key pieces of information about the decedent's personal history, which can provide specific observations and temporal information pertaining to circumstances shortly before death. Accordingly, while performing the interviews, the forensic expert should exercise judgment in assessing the interviewee's credibility and assigning commensurate weight to the information elicited. Such evidence should be integrated with that gleaned from other sources, particularly the death scene, physical autopsy, postmortem toxicology, and observations of other informants who had significant contact with the decedent in the days and weeks prior to death. Use of these supplemental sources offers some assurance that the ultimate interpretations will be valid (Beskow et al. 1990).

POSTMORTEM TOXICOLOGY

Another source of evidence requiring careful interpretation is the postmortem toxicology results. The role of intoxicants is often central in determining the decedent's intent at the time of death, both with respect to mental capacity and lethality. If drug or alcohol use is suspected, the psychological autopsy should address whether the decedent was too intoxicated to have formed intent and whether the suicide was by drug overdose. Thus, it is useful for the forensic expert to have some working knowledge of basic toxicology. It is also important to be aware of misconceptions and pitfalls, e.g., so-called "lethal" levels of drugs; use of postmortem toxicology results to estimate antemortem concentrations or drug dosage; and the routine and uncritical use of toxicology textbooks or tables to determine cause of death (e.g., see Berman et al. 2003; Palmer 2010; Gill et al. 2013). Discussion with an experienced forensic toxicologist and/or forensic pathologist, review of corresponding expert reports, and/or review of the relevant scientific literature will also assist the forensic expert in understanding the case.

The most challenging part of postmortem forensic toxicology is interpreting the results and explaining what they

mean to nonspecialists, such as legal professionals and juries (Drummer et al. 2013). This requires a broad knowledge of the pharmacology and toxicology of licit and illicit drugs, their mechanism of action in the body, and their potential for causing intoxication and death. Tables of therapeutic, toxic, and fatal concentrations of drugs are available, although these should be used cautiously (Schulz et al. 2012). The notion of "lethal drug levels" or some concentration threshold that leads to incapacitation and death is hard to defend, because so much depends on the dose taken, route of administration, development of tolerance, body weight, and the nature of any concomitantly ingested substances. Development of tolerance is especially important with regard to toxicity of opioid drugs (Davis 2014). Certain drug combinations are more dangerous than others, such as when ethanol is taken with sedative-hypnotics (barbiturates or benzodiazepines) or when selective serotonin reuptake inhibitor (SSRI) antidepressants are taken with the painkiller tramadol, which may cause a life-threatening "serotonin syndrome" (Pilgrim et al. 2010).

The validity of the toxicological results is contingent upon the appropriate selection and collection of specimens for toxicological analysis. In the postmortem context, blood is the most important specimen for analysis, because the concentrations of drugs present in the blood typically are a direct reflection of the concentrations reaching the brain. Depending on the concentrations of centrally acting drugs in blood, tentative conclusions can be drawn about toxicity and potential lethality. However, the results of toxicological analysis are susceptible to several sources of error, ranging from the way the specimen is collected to the interpretation of assay results.

Sampling site and handling of the blood specimen can have significant effects on the reliability of the analytical results. The preferred source of blood for postmortem analytical toxicology is from a peripheral sampling site, such as a femoral vein. The worst possible source is from the chest cavity, because of the risk of contamination from drugs unabsorbed in the stomach or at higher concentrations in lung and liver than in the blood (Kugelberg and Jones 2007). Biological fluids taken for toxicological analysis should be preserved with sodium or potassium fluoride (1%–2%) and then refrigerated or frozen (Drummer 2010). Fluoride ions act as enzyme inhibitors, which help to prevent bacterial metabolism of glucose into ethanol, especially if the body is decomposed or microorganisms have spread from the gut into the blood. Because of the risk of alcohol being produced in the body after death, a realistic cut-off concentration should be used when reporting a positive blood alcohol concentration (BAC) at autopsy, e.g., 0.01 gram %. However, there is much to recommend use of a higher cutoff, such as 0.02 gram %, especially in traumatic deaths (Kugelberg and Jones 2007).

A positive BAC should be confirmed by analysis of ethanol in alternative specimens, such as stomach contents, urine, and/or vitreous humor. The sugar content of urine voided by healthy individuals is negligible, so there is no substrate for postmortem synthesis of ethanol. Given the anatomic separation, there is low likelihood of bacteria spreading from the gut to the eye and introducing newly synthesized ethanol to the vitreous humor. Analysis of biomarkers of ethanol ingestion, such as the nonoxidative metabolites ethyl glucuronide (EtG) and ethyl sulfate (EtS), can also help to ascertain if ethanol is the product of postmortem fermentation (Maenhout et al. 2013). Both EtG and EtS are produced when ethanol undergoes metabolism in the liver, so their presence in postmortem blood specimens indicates that the decedent had probably ingested alcohol while alive (Krabseth et al. 2014).

To analyze drugs and their metabolites in the circulatory system, whole blood is utilized in postmortem forensic toxicology, whereas plasma or serum is utilized in clinical pharmacology and therapeutic drug monitoring programs. Because many drugs bind to plasma proteins, the concentrations in plasma or serum are higher than in red cells and in whole blood. Unfortunately, this difference is often ignored, making it difficult to compare postmortem drug concentrations with therapeutic drug concentrations. For example, plasma-to-blood distribution ratios are 1.15:1 for ethanol, 1.8:1 for diazepam, and 2:1 for tetrahydrocannabinol (THC), the major psychoactive drug in marijuana.

Another factor to consider is the phenomenon of "postmortem redistribution," which refers to movement of drugs out of body tissue depots and into the blood after death (Pélissier-Alicot et al. 2003). Concentrations of drugs sequestered in body organs and tissues are higher than those in peripheral blood. Consequently, redistribution after death results in higher postmortem central (e.g., heart) blood concentrations that may overestimate the actual blood concentrations at the time of death. The extent of postmortem redistribution is gauged by comparing heart blood concentration to femoral blood concentration. High heart-to-femoral ratios suggest that postmortem redistribution has occurred (Han et al. 2012).

Other valuable biological specimens in postmortem toxicology include hair, fingernails, and urine. Hair strands are particularly useful when subjected to segmental analysis, which allows the creation of an approximate timeline of drug intake during life (Barbosa et al. 2013). The trace analysis of drugs in hair strands can be used to verify the decedent's compliance with medications, such as antidepressants or antipsychotics (Barbosa et al. 2013). Hair is a viable specimen even if the body is decomposed and blood specimens too contaminated for sampling and proper analysis. Both hair and nails are obtainable from exhumed bodies, allowing detection of drug intake long after death.

Urine specimens are readily available at autopsy for analysis in large volumes, with concentrations of drugs and metabolites that are higher than in blood samples, and with longer time windows for detection. However, the composition of urine is variable depending on fluid intake and

state of hydration. Some urine samples are more dilute than others (some authors suggest normalizing drug test results according to creatinine concentration), and the urinary pH affects drug concentrations, especially the excretion of basic drugs. A positive postmortem urine drug test furnishes proof that particular drugs were used but does not establish exactly when they were used; whether the decedent was acutely intoxicated at the time of death; or the specific degree of drug-related impairment experienced by the decedent at the time of death. Moreover, postmortem urine drug concentrations cannot be extrapolated to determine the dosage of the drugs consumed or the drug concentrations in the blood at the time of death.

The results of postmortem toxicology are indispensable to the psychological autopsy, because they provide important information as to cause of death (e.g., acute poisoning) as well as the decedent's mental state at the time. However, the forensic expert should be aware of common sources of error in the collection and processing of specimens and in the interpretation of the analytical results. Such awareness will help ensure that reliable toxicological evidence is used for the findings and opinions set forth in the psychological autopsy.

ETHICAL CONSIDERATIONS IN SURVIVOR INTERVIEWS

Care must also be taken to protect the interests of the survivors during the psychological autopsy. Out of respect for the bereavement process, and to minimize survivors' tendency to idealize their loved one in the early stages of grief, the investigator should allow 2 to 6 months to elapse before contacting survivors (Beskow et al. 1990). The investigator should respect categorically any refusal to participate or request to withdraw from participation. Informed consent should be obtained, with the advisement that the interview is not intended to be therapeutic. Therapeutic effects of the survivor interviews may be inevitable, as survivors often experience them as cathartic, allowing ventilation of difficult feelings about the decedent and his or her death. Survivors may participate in order to contribute to the state of knowledge concerning suicide risk and prevention, thereby sublimating feelings of grief, anger, or abandonment, and salvaging some greater good from personal tragedy (Wong et al. 2010).

The interviewer should neither disavow nor deliberately avoid these salutary benefits, but should keep them from clouding the purpose of the evaluation or confusing the interviewee. The risk is that the interviewee will mistake the interview for treatment and perhaps even identify the interviewer as a therapist, leading to disclosures that are either outside the intended scope of the interview or affirmatively counter to the interests of the interviewee (e.g., if an insurance beneficiary admits a belief that the death was in fact a suicide). Nevertheless, the interviewer should be alert to any mental health needs that become apparent during the interview. The interviewer stands in a position in such cases to recommend that the interviewee seek psychological counseling, while consistently maintaining a forensic, as opposed to therapeutic, stance during the encounter.

REPORT WRITING

The investigation culminates in a detailed written psychological autopsy report, which should state the purpose of the evaluation and present the psychiatric–legal question (e.g., "Did the decedent possess a mental state consistent with suicide at the time of death?"). A discussion of the cause of death, including findings from the scene investigation, witness statements, physical autopsy, and toxicology report, should be included before entering into a detailed but concise synthesis of relevant biographical information about the decedent, including major active psychosocial stressors, relationship status, mental health history, and impressions from survivor interviews. The report should pay particular attention to life events in the days, weeks, and months immediately preceding death. In accordance with the American Academy of Psychiatry and the Law's "Ethical Guidelines for the Practice of Forensic Psychiatry," the forensic expert should acknowledge that a personal examination of the decedent was not conducted (Ogloff and Otto 1993). If an instrument such as the ECDS is used, a brief discussion of the relevant protocol and associated reliability and validity data should be included.

At the end, the report includes a summary of the behaviors and mental state of the decedent at the time of death and whether they were consistent with suicide. The expert should address "factors descriptive of high intentionality, which include conscious awareness of consequences; goal of cessation; expectation of fatal outcome; implementation of a method of high lethality; minimal rescuability or precautions; premeditation [i.e., planning]; and communications [of intent]" (Berman 2005, 369). The report should provide a probabilistic assessment of suicide risk (e.g., mildly, moderately, or severely elevated) at the time of death. The level of certainty should be commensurate with the setting in which the opinion is offered, with a confidential report to the coroner countenancing a slightly wider range of certainty than expert testimony in court. In formal legal proceedings, the forensic opinion should be offered with a "reasonable degree of medical certainty" (or "medical probability," depending on the legal jurisdiction), which is generally equivalent to "more likely than not." The forensic expert should not overstate the level of confidence in the assessment or create a misleading impression of certainty about suicide (Berman 2005).

ADMISSIBILITY AND TESTIMONY

If the psychological autopsy will be offered as expert opinion evidence in a contested legal matter, it must satisfy the

requirements of legal admissibility, which in the United States, depending on the jurisdiction, is governed by one of two evidentiary standards. The older *Frye* standard, still observed in a number of states, uses the criterion of "general acceptance" in the field (*Frye v. United States*, 293 F. 1013 [D.C. Cir. 1923]). Under the newer *Daubert* standard, used in federal courts and adopted by many states, the court must find that the expert is properly qualified and that the opinion will assist the finder of fact (*Daubert v. Merrell Dow Pharm., Inc.*, 509 U.S. 579, 1993).

To qualify as an expert, the proffered witness must possess the "knowledge, skill, experience, training, or education" to offer understanding and insights above what would be obvious to the layperson (Federal Rules of Evidence 702). The forensic expert should be prepared to discuss his or her qualifications in mental health and suicidology, as well as in the conduct and analysis of the psychological autopsy. Thus, before undertaking a psychological autopsy, the forensic expert would be well served to obtain additional knowledge, training, and/or experience in suicidology and psychological autopsy, as well as basic aspects of the coroner investigation.

Whether the psychological autopsy will assist the finder of fact hinges on "a preliminary assessment of whether the reasoning or methodology underlying the testimony is scientifically valid" (*Daubert*, 509 U.S. at 12). To determine scientific validity, *Daubert* set forth a nonexhaustive list of factors for consideration, including testability, peer review, known error rate, standardization, and general acceptance (*Daubert*, 509 U.S. at 12–13). Generally, the *Daubert* standard favors admission of scientific opinion evidence, commonly shifting discretion to the finder-of-fact to determine weight and credibility.

The forensic expert nevertheless should be prepared to defend the use of the psychological autopsy in terms of its general acceptance in the field, the validity of its techniques and practices, or both. That defense may include a frank acknowledgement of the psychological autopsy's limitations, including the lack of a standardized protocol, the absence of consensus on terminology, and the inability to determine with certainty that the death was a suicide. That said, the psychological autopsy is no less valid than other forensic mental state evaluations, such as for criminal insanity or testamentary capacity. Moreover, the psychological autopsy has for decades been used and generally accepted as the state of the art in the postmortem assessment of mental state. Furthermore, the psychological autopsy has been subjected to peer review, inasmuch as several hundred research reports relying on the psychological autopsy have been published in peer-reviewed journals. Finally, though the decedent has usually not been examined personally, such direct access to the decedent's thoughts is not necessary for the forensic expert to arrive at an opinion on the decedent's mental state to a reasonable degree of medical certainty after careful analysis of the available evidence in its totality (Jacobs and Klein-Benheim 1995).

SUMMARY

The psychological autopsy is a forensic retrospective investigation and assessment, which serves as a powerful tool to assess the likelihood that a sudden, unexplained death is a suicide, as well as to understand the factors that contributed to the suicide. With its systematic approach to examining the psychological and contextual circumstances preceding suicide, the psychological autopsy has assisted in analyzing equivocal death cases and has helped survivors understand the decedent's behavior. Additionally, it has been used in a variety of legal, quality improvement, and research contexts. Despite potential criticism with respect to methodology, courts have frequently found the psychological autopsy to be scientifically valid and helpful to the finder of fact in legal settings. Though unable to make a definitive determination that any particular death was a suicide (which would go to the ultimate issue in litigation), the psychological autopsy can make a probabilistic assessment of suicide risk and can provide useful insights to coroners, courts, researchers, and survivors.

Informed consent and competence

PRAVEEN R. KAMBAM

INTRODUCTION

> Every human being of adult years and sound mind has a right to determine what shall be done with his own body.
>
> Justice Benjamin Cardozo
> *Schloendorff v. Society of New York Hospital*, 1914, 93

Justice Cardozo's well-known quote illustrates the long-established right to self-determination of competent patients. That is, they should be free to make informed treatment decisions for themselves. Although this principle is seemingly straightforward, especially in a society such as the United States where a significant emphasis on individual rights exists, its translation into clinical practice is more complicated.

Attorney Paul Gebhard is credited with the first use of the legal term "informed consent" in a 1957 California medical malpractice case (Pace 1997), though underpinnings of the modern-day concept of informed consent have been cited throughout history (Faden and Beauchamp 1986). The Court in that case, *Salgo v. Leland Stanford Junior University Board of Trustees*, held that a physician cannot withhold any facts from a patient that are necessary to form the basis of an intelligent consent. Since then, the informed consent doctrine has evolved, influenced by new case law, ethical considerations, and changing standards of clinical practice (Meisel and Kabnick 1980).

Informed consent is particularly germane to the profession of psychiatry, a field with somewhat conflicting positions related to informed consent. In the psychoanalytic tradition, on which many psychotherapies are based, extensive disclosure by a psychiatrist is minimized, and patient efforts to obtain information about treatment may be interpreted as resistance. But, psychiatrists historically have utilized discussion-based interventions, rooted in a therapeutic relationship. These interventions often acknowledge patients' autonomy and personal responsibility for treatment decisions. In this regard, psychiatrists are more accustomed to issues related to informed consent and may place greater weight on patient autonomy than physicians in other specialties. As consultants to other medical specialties or services, psychiatrists often are called upon to assess capacity to consent to or refuse treatment, and therefore are relatively comfortable weighing and balancing the competing concerns underlying competency disputes.

LEGAL STANDARDS OF INFORMED CONSENT

In early court cases that focused on bodily integrity, like *Schloendorff*, the failure of a physician to obtain patient consent could result in the physician's committing the intentional tort of battery. However, a "battery standard" seemed inappropriate to apply to physicians not intending to harm patients and did not adequately incorporate the importance of patient knowledge and autonomy. Therefore, courts instead began to utilize a "negligence standard" that respected the importance of patient autonomy more.

PHYSICIAN-BASED STANDARDS

The Salgo case

Martin Salgo was a 55-year-old man with spinal cord injury who experienced lower body paralysis from a translumbar aortography. He claimed that he had not been informed of the risks of the diagnostic procedure beforehand. In *Salgo*, the court ruled that physicians may be liable if they withhold any facts that are "necessary to form the basis of an intelligent consent" to the proposed treatment. The court emphasized that the patient's right to consent required full disclosure of the relevant facts necessary to make an informed decision.

The professional standard or reasonable medical practitioner standard

Three years later in *Natanson v. Kline* (1960), a Kansas court delineated required elements of disclosure by establishing what has come to be known as the "professional standard"

or the "reasonable medical practitioner standard." After suffering severely disabling burns from cobalt irradiation following a mastectomy, Irma Natanson claimed to have been inadequately informed of the risks of the treatment. The court held that the required elements of disclosure included the nature of the patient's illness, the nature of the proposed treatment and its likelihood of success, the risks of untoward outcomes, and the availability of alternative modes of treatment. The court limited the amount of information required to be disclosed to what a reasonable medical practitioner would disclose under similar medical circumstances.

The reasonable practitioner standard gives physicians discretion in determining what information to provide to patients and, by defining the legal standard of care in reference to the actions of other physicians, assumes that a consensus exists within the medical field as to what constitutes appropriate disclosure. This standard has been criticized as focusing too much on the physician rather than on the goal of informed consent (i.e., patient autonomy). The reasonable medical practitioner standard still exists in roughly half of the states.

PATIENT-BASED STANDARDS

The reasonable person standard

In 1972, the U.S. Court of Appeals for the District of Columbia, in *Canterbury v. Spence*, heard a case that involved Jerry Canterbury, a 19-year-old man who became partially paralyzed as a result of complications that occurred during thoracic spine surgery. His physicians failed to warn him of any risk of paralysis from the procedure. The Court rejected a physician-based standard and proposed that standards of disclosure be based on what a "reasonable person" would find material to clinical decision making.

The *Canterbury* ruling replaced the physician-based standard with one that focused on patients' autonomy to weigh for themselves the risks and benefits of a proposed treatment. In other words, this "objective patient-based standard" considered what information a typical patient would need to know in order to understand the medical decision at hand. Only risks potentially affecting the decision making of a hypothetical reasonable person would be considered material.

The reasonable person standard assumes that all patients weigh benefits and risks similarly, and does not tailor the informed consent process to the individual needs of the particular patient who actually will undergo the proposed treatment. As a result, this objective standard shields physicians from the whims of individual patients, probably in an effort to balance expansion of the patient's right to reasonable disclosure with concerns about expansion of malpractice liability (President's Commission 1982). The reasonable person standard, which exists in roughly half of the states, can be viewed as a middle position, existing somewhere in between the extreme positions of allowing physicians to disclose whatever they consider material and requiring disclosure of all information relevant to that particular patient's decision, regardless of how idiosyncratic that information may be (Appelbaum and Gutheil 2007, 127).

Subjective patient-based standard

In 1979, the Oklahoma Supreme Court established a "subjective standard" in *Scott v. Bradford*. In this case, Norma Jo Scott underwent a hysterectomy because of uterine fibroids. After the procedure, she began having incontinence because a fistula formed between her bladder and vagina. The patient claimed that she was never informed of this potential complication of the surgery. The Court held that a physician must disclose a "material risk" of a proposed treatment, defining "material risk" as one that would "be likely to affect a patient's decision." This subjective patient-based standard did not offer physicians the protection that the reasonable person standard afforded them. That is, if a material risk was not disclosed, a physician could be held liable if that particular individual patient would have declined the proposed treatment had it been disclosed.

Although the subjective standard gives significant deference to patient autonomy, it is challenging to implement and imposes upon physicians a disclosure requirement that is potentially based on individual patient whims and hindsight bias. Because of these difficulties, the subjective patient-based standard is not utilized in most jurisdictions, with only Oklahoma and Oregon requiring disclosure that resembles a subjective informed consent standard.

INFLUENCES ON THE EVOLUTION OF INFORMED CONSENT

The legal doctrine of informed consent and its application to clinical practice have evolved in the United States in the context of a variety of social, historical, and cultural forces (Katz 1984a; Faden and Beauchamp 1986; Appelbaum et al. 1987). During the twentieth century, a paternalistic model of physician-driven decision making began to shift to a more patient-centered model of care. In a culture that became less deferential to authority figures, the former model of uncontested physician power eroded, with lawsuits, research, and even statements from physicians highlighting this model's excessive cost and harm to patients.

An important precedent in the twentieth century was the development of the Nuremberg Code, which established informed consent requirements for human research (later reflected in consent requirements for treatment).

The changing structure of our health-care delivery systems also had significant influence on the evolution of informed consent. In the 1980s, rising health-care costs led economic stakeholders to question physicians' decision making in the name of cost containment. Time constraints, heightened by increased time and resources that were required to be devoted to paperwork, precertifications,

and utilization management, have limited the opportunity for discussion and reflection in doctor–patient encounters.

The rise of medical consumerism—the notion that patients are consumers of services and as such, have the ability to choose what services they receive and from whom to receive such services—has increased demands for information and patient participation in decision making (Rodwin 1994). With the advent of the Internet, a rapid explosion of health and health care-related websites—accessible via portable technology—has drastically altered the manner by which patients can gather information to make medical decisions (Cohen et al. 2010; Parikh 2013).

Last, mirroring broader cultural changes, the American public's level of trust of its physicians has declined and now is among the lowest in industrialized countries (Blendon et al. 2014).

COMPONENTS OF INFORMED CONSENT

To consent to a proposed treatment, the informed consent doctrine requires that a patient's consent be "informed" and voluntarily given (i.e., free of coercion) and that the patient be competent to make the medical decision. Thus, three fundamental components of informed consent exist: information (disclosure), voluntariness, and competence.

Information (disclosure)

Appropriate disclosure of information to the patient is central to the process of informed consent. Elements required to be disclosed were articulated in the *Natanson* case and, in modern clinical practice, typically include potential benefits and indications of a treatment, risks of adverse outcomes, and alternatives, including no treatment (Meisel et al. 1977). Naturally, questions arise regarding what type and amount of information is legally sufficient, the answers to which are reflected in the varying state standards for informed consent discussed above.

Voluntariness

To be voluntary, consent must be free of duress, fraud, or coercion. When extreme, examples of duress and coercion seem relatively clear; however, they often can be more subtle and less straightforward. The psychiatrist must refrain from using coercion but can employ an appropriate level of persuasion in attempting to influence patient behavior positively and advocate for an appropriate treatment. Malcolm (1992, 241) defined coercion as a situation in which the psychiatrist aims "to manipulate the patient by introducing extraneous elements which have the effect of undermining the patient's ability to reason," and persuasion as a situation in which the psychiatrist aims "to utilize the patient's reasoning ability to arrive at a desired result." Applebaum and Gutheil (2007, 127) note that the subtlest forms of coercion exist in all interpersonal relationships and probably should not be considered by the legal system—instead, only illegitimate forms of pressure constitute coercion that may void a patient's consent.

Certain elements of the psychiatrist–patient relationship, patient regression during illness, and impacts of institutionalization all may make coercion more likely. In *Kaimowitz v. Michigan Department of Mental Health* (1973), the Court found that it would be impossible for an involuntarily hospitalized psychiatric patient to make an "uncoerced" decision when the patient's release from the hospital might depend on consenting to experimental psychosurgery. The Court opined that part of the reason for this is that such a patient lives in an inherently coercive institutional environment.

Competence

Patients must be competent to consent. From a legal standpoint, adults are presumed to be competent unless adjudicated otherwise, whereas minors are presumed to be incompetent regardless of their actual capacity. Of note, "incompetence" is a legal determination and refers to a court's adjudication, and "incapacity" refers to a clinician-determined functional inability (Mishkin 1989). Such *de jure* competence (or incompetence) usually refers to global or general competence. Despite the presumption of *de jure* competence, adult patients may in fact (de facto) lack competence to make specific treatment decisions. Here, psychiatrists may be consulted to evaluate a patient's capacity to refuse or accept a specific treatment. Some advocate the use of the term "decisional capacity" to avoid confusion surrounding the term "competence" (and to distinguish from competence to perform an act or series of acts, such as parenting).

STANDARDS FOR COMPETENCE

Roth et al. (1977) summarized the criteria by which competence assessments are made. These criteria are that the patient (a) actually evidences a choice, (b) evidences a choice that the clinician believes will lead to a reasonable outcome, (c) appears to apply rational reasoning to the decision-making process, (d) has the ability to understand the information that has been disclosed, and (e) actually understands that information. Appelbaum and Roth (1982a,b) emphasized appreciation of information, over and above understanding of information, as an important criterion in competence assessment.

Taken together, the above competence assessment criteria encompass four fundamental standards for determining competence in decision making. In order of increasing capacity required, these activities are communication of a choice; understanding relevant information provided; appreciation of the situation and its consequences; and rational decision making (Appelbaum et al. 1987, 84–87). Communication of a choice requires indication of a preferred option with enough stability in this decision for a proposed treatment to be implemented. Understanding the relevant information provided requires a factual understanding of the elements

of the informational component of informed consent. Appreciation of the situation and its consequences requires a patient to possess insight into his or her condition and the likely consequences of treatment options, as applied to the patient's specific situation. Finally, rational decision making or reasoning requires a rational process of information manipulation related to the proposed treatment option.

CHOOSING STANDARDS FOR COMPETENCE

Because competence is not a medically determinable state, it represents a certain threshold of functioning at which we, as a society, are willing to allow a person to make a particular decision. Because this threshold balances patient autonomy, third-party interests, and state interests, it reflects societal policy considerations.

Similarly, models for selection of criteria by which a patient's decisional capacity will be judged reflect the principle that, as the consequences of a patient's decision to consent to or refuse treatment become more serious, the criteria for assessing capacity should become more stringent. Roth et al. (1977) formulated a model selecting criteria using a risk–benefit ratio of treatment based on the risk inherent in the treatment decision. Drane (1985) revised this model into a sliding scale. The President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research (1982) recommended linking the criteria chosen to assess capacity and the consequences of the patient's potential decision. In another version of the sliding scale, Grisso and Appelbaum (1998) employ the model of a balance scale, with autonomy at one end and protection at the other. The patient's decision-making capacities add to the autonomy end, while increasing risk in the decision adds to the protection end. Although variably stringent criteria inherent in a sliding-scale model could be abused because the evaluator is the one who sets the standard used to determine incapacity, the model also allows for clinically appropriate balancing between the promotion of health and autonomy.

In such sliding scale models, the standards of competence that are less restrictive or most protective of the patient's autonomy (e.g., evidencing a choice) would be employed in certain very low-risk decisions. Alternatively, in certain very high-risk decisions, the highest form of understanding, appreciation, would be employed (Appelbaum and Roth 1982a; Drane 1985; Grisso and Appelbaum 1998).

STANDARDIZED ASSESSMENT INSTRUMENTS

Although decisional capacity is most often assessed through a clinical interview, several standardized instruments are available to aid in assessing competence to consent to treatment. Such structured instruments provide a framework to ensure that relevant issues are covered, and may be especially helpful in difficult cases or cases likely to be resolved in court.

In a review, Dunn et al. (2006) identified nine instruments that assessed communication of choice, understanding, appreciation, and reasoning. The authors found the *MacArthur Competence Assessment Tool–Treatment* (MacCAT-T) possessed the most empirical support. The MacCAT-T takes approximately 20 minutes to complete and includes a chart review and a semistructured interview (which incorporates information specific to the patient's situation), resulting in scores in each of the four fundamental domains of competence assessment (Grisso et al. 1997).

Although the Mini-Mental State Examination (MMSE) was not developed to identify incompetence, it may have some utility in identifying patients at the low and high ends of the range of capacity. For example, scores less than 19 on the MMSE have been found to correlate with clinical judgments of incapacity (Etchells et al. 1999; Kim and Caine 2002).

THE PROCESS MODEL OF INFORMED CONSENT

Obtaining informed consent is sometimes conceptualized as a specific, time-limited event. For example, the treating physician comes to the bedside and discloses information to a patient, who acknowledges understanding it and then signs a form documenting his or her consent. In this "event model" the signing of a consent form is all too often substituted for a truly informed consent process. Even though physicians and patients may view the primary purpose of a consent form as protection of doctors from lawsuits (Harris et al. 1982), a signed, generic consent form, in and of itself, rarely provides adequate legal protection against malpractice claims of failure to obtain informed consent.

Lidz et al. (1988) proposed that instead of an event model, informed consent should be conceptualized as a "process model." Here, informed consent is viewed as an ongoing process or dialogue between physician and patient, which continues throughout the course of treatment. A physician presents information to a patient in a discussion-like format, tailored to the patient's needs, sophistication, and level of intelligence (Stanley 1983). In the process model, the patient has an opportunity to ask questions and understand the rationale behind the proposed treatment options, and is given adequate time for consideration and consultation with family and friends, if applicable. Additionally, the level of uncertainty related to the mental health diagnosis, treatment, and prognosis is shared by the physician with the patient.

EXCEPTIONS TO INFORMED CONSENT

There are five generally recognized exceptions to informed consent. Incompetence is the most obvious exception. Because patients must be competent in order to give informed consent, they cannot provide it if they lack decisional capacity. If a patient is incompetent to consent, a physician can attempt to obtain substitute consent from a court-appointed guardian for medical decision making or from next of kin. Of note, a patient's decisional capacity may change during the treatment process as a result of treatment

(Appelbaum and Roth 1981), as a result of the natural evolution of the patient's mental disorder (Roth 1985), or as the nature of the treatment decision facing the patient changes (Schwartz and Blank 1986).

The second exception is emergency medical situations. When there is an imminent danger of serious harm to an incapacitated patient or others, treatment (limited to that which is necessary to address the imminently dangerous condition) may be given until the emergency passes. As a matter of law, the patient's consent to treatment is implied during an emergency when consent cannot be obtained. However, what constitutes a medical emergency is somewhat less clear in psychiatry than in general medicine or surgery.

Patient waivers are the third exception to informed consent requirements. The right to informed consent belongs to the patient. As such, a patient may waive the right to information and/or the right to consent.

Therapeutic privilege is the fourth exception. Therapeutic privilege is the doctrine by which the physician may withhold information from a patient when to provide it would be so clearly detrimental to the patient that the disclosure would be antitherapeutic. This exception is especially applicable if the information to be conveyed would cause a high degree of psychological distress and, as a result, impair the patient's decision-making capacity. Because therapeutic privilege can easily be abused, courts have allowed this exception in very limited circumstances. It is clearly not intended to allow physicians to withhold information simply because of their belief that the provision of such information would lead to the patient's refusing treatment. Indeed, in *Canterbury*, the court noted that therapeutic privilege was limited "lest the privilege devour the disclosure rule itself."

The final exception is involuntary treatment without informed consent based on statutory provisions that exist in some states. Here, a patient's refusal of treatment (and autonomy) is overridden by judicial, clinical, or administrative decision because of counterbalancing policy goals.

CLINICAL APPLICATIONS

Consultations to other medical services

Treatment refusal by hospitalized patients on general medical or surgical services commonly results in a psychiatric consultation request for competence assessment. Concerns that a consenting patient may lack capacity also can lead to consultation requests, though this occurs less frequently. When performing the consultation, it is often necessary for the consulting psychiatrist to remind the referring physician that although the consultant renders an opinion regarding the patient's decisional capacity and may opine as to the likely outcome were a competence hearing to be conducted, only the court can declare individuals legally incompetent. Additionally, though the psychiatric consultant may evaluate the patient's decisional capacity and recommend interventions that may enhance that capacity, it remains the patient's treating physician's obligation to obtain the patient's consent for the proposed treatment.

During decisional-capacity assessments, elements of the psychiatric interview sufficient to establish the patient's mental status should be performed. Because competence is influenced by alterations in the patient's mental status and responses to treatment, it is sometimes helpful to evaluate the patient serially (Schwartz and Blank 1986).

The psychiatric consultant should assess the evaluee for overlooked general medical conditions (e.g., delirium) that may impact decisional capacity and, if present, provide recommendations for their further workup and treatment. Because decisional-capacity assessment is task specific, it is helpful to obtain the relevant information about the nature of the proposed treatment from the referring physician. Appelbaum and Roth (1981) have emphasized the importance of clarifying with the referring physician the nature and extent of the information that actually has been presented to the patient, because it would be impossible to assess the patient's understanding without knowing the nature of the disclosure that has been made. At times, ascertaining the meaning of the patient's consent or refusal may facilitate a psychodynamically informed intervention that could enhance the patient's decisional capacity.

Minors

Informed consent requirements for minors are different than for adults. In contrast to adults, minors are presumed incompetent by law. This legal tradition reflects the perspective that an individual under the age of majority (which is, in most cases, 18 years old) cannot adequately appreciate the ramifications of refusing or accepting treatment, and therefore, such decisions are better left to those legally responsible for the minor. Indeed, some of the challenges that treating clinicians in these situations face arise because authority to make medical decisions stems from a third party, not the minor patient himself or herself. Although the responsible third party provides informed permission for treatment, minors should be included in the decision-making process at a developmentally appropriate level, and assent should be sought and obtained when possible.

Potential exceptions to informed consent for minors include (a) emergency situations; (b) emancipated minors (minors no longer receiving parental guidance or financial support); (c) mature minors; (d) specific consent statutes (e.g., treatment for substance abuse, sexually transmitted illnesses, contraception, etc.); and (e) foster care exceptions. Specific-consent statute exceptions aim to encourage desired treatment in specific situations where requiring parental or guardian consent may discourage such treatment.

Geriatric populations

Competence issues surrounding end-of-life decisions, nursing home placement, protracted periods of incapacity generated by dementing illnesses, and testamentary capacity

are all issues that arise commonly when treating the elderly and nursing home patients, the number of whom are growing rapidly. Psychiatrists may encounter patients with various degrees of cognitive impairment, including those with a legal guardian. In addition to cognitive limitations, physical impairments (e.g., presbycusis, visual deficits, etc.) may present challenges to patients' comprehension of information. Therefore, the informed consent process should include providing information individually tailored to each patient's level of understanding and requiring confirmation of each patient's comprehension of the delivered information. Christensen et al. (1995) found that older patients who were particularly vulnerable to potential incompetence included those with lower vocabulary levels, lower educational levels, chronic or acute medical illness, and cognitive impairment. The authors suggested that clinicians and researchers be especially diligent in obtaining and assessing informed consent from older individuals with these characteristics.

The Patient Self-Determination Act (PSDA), passed by Congress in 1990, supports the participation of competent elderly patients in medical decision making through the use of advance directives, which consist of instructional directives and proxy directives that designate healthcare decision-making surrogates. Many questions have been raised about the validity of advance instructional directives, particularly because of the difficulty in being fully informed of and appreciating the future medical contingencies that may exist at the time the directive is actually employed. Although proxy decision makers are theoretically important for extending patient autonomy, studies have demonstrated that surrogates have poor predictive abilities to exercise substituted judgment, even after advance directive instructions are discussed (Teno et al. 1994; Covinsky et al. 2000). Even though some authors question the primacy of advance directives and advocate "best interest" judgments (Dresser and Whitehouse 1994; Tonelli 1996), case law still supports the exercise of substituted judgment.

Voluntary hospitalization

Whether patients need to be competent to consent to voluntary psychiatric admission is unclear. However, many states require that patients give written informed consent for voluntary admission. In *Zinermon v. Burch* (1990), the U.S. Supreme Court seemed to suggest that in such states, patients may require screening for competence in order to voluntarily admit themselves to a psychiatric hospital. Although the impact of the *Zinermon* case on clinical practice has been limited, concerns about potential impacts led the American Psychiatric Association (APA) to establish the "Task Force on Consent to Voluntary Hospitalization." The recommendations of the task force, which were approved by the APA's Board of Trustees in 1992, included one that suggested that clinicians conduct a brief clinical assessment of the patient (based on the requirement that the patient understand that he or she was being admitted to a psychiatric hospital) and evaluate whether the patient expressed agreement with the admission through verbal, written, or behavioral actions (APA 1993).

A clinical practice that violates the spirit of informed consent is the use of the threat of commitment to coerce a patient into a voluntary admission (Schwartz and Roth 1989). This may occur when a patient is clearly in need of psychiatric hospitalization but does not meet the criteria for involuntary admission. Even though the clinician may be wary of the clinical and legal consequences of discharging the patient from the emergency room (Rachlin and Schwartz 1986), informed consent requires voluntariness (i.e., the absence of coercion) and a disclosure of treatment options; therefore, this practice may void consent for hospitalization.

Research

Psychiatric clinical researchers face the challenge of obtaining informed consent from participants with potentially diminished mental abilities and impaired decision making. Ethical and practical challenges abound in obtaining informed consent for psychiatric research (Pinals and Appelbaum 2000; Gupta and Kharawala 2012; Gupta 2013). One unique challenge facing researchers is the task of minimizing "therapeutic misconception" (i.e., the failure to understand the difference between research participation and treatment). Research involving subjects with impairments in capacity to consent can increase this challenge (National Institutes of Health, Office of Extramural Research 2009).

Researchers must strike a balance between the goals of promoting scientific advancement, minimizing study subjects' risks, and maximizing the subjects' autonomy. The National Bioethics Advisory Commission (1998) has provided some guidance to researchers by issuing a report regarding informed consent, capacity, and surrogate decision making when engaging in research involving persons with mental disorders that may affect decision-making capacity.

"Extraordinary" treatments

Some state courts and legislatures have deemed several psychiatric treatments "extraordinary." As such, these treatments require special review or procedures beyond that of a treating physician unilaterally determining whether a patient's consent is adequate. These treatments variously have included sterilization, psychosurgery, electroconvulsive therapy (ECT), and treatment with antipsychotic medication. For example, in *In re Branning* (1996), an Illinois appellate court ruled that guardians cannot consent to ECT for their wards without the ward's specifically being found incompetent to make such a treatment decision. In *Matter of A.M.P.* (1999), another Illinois appellate decision, the Court held that parents of a 16-year-old could

not consent to ECT for their child (who was noncommunicative, psychotic, and failing other treatments) without judicial review.

Psychotherapy

Statutes and case law generally do not provide clear guidance on whether or not informed consent for psychotherapy is legally required. However, the ethical guidelines of the American Psychological Association (2010, 13) explicitly require it, and those of the American Psychiatric Association (2013) implicitly require it.

There may be several reasons that the typical elements of the informed consent doctrine are not consistently required of psychotherapy. A partial explanation may involve concerns that informed consent may undermine transference and be duplicative of the extensive disclosure inherent in the psychoanalytically based approaches of many psychotherapies (Robitscher 1978). Additionally, clinicians may be uncomfortable disclosing the uncertainty of predicting the benefits of, risks of, and prognosis in psychotherapy (Katz 1984b). Another explanation is that psychotherapy is not viewed as a procedure or intervention with significant risks. Finally, malpractice claims involving psychotherapy historically have had limited success, though recently the size of monetary awards in "recovered memory" litigation has grown (Beahrs and Gutheil 2001), and failure to inform about medication treatment options (as opposed to psychotherapy) has been grounds for lawsuits in the past (Malcolm 1986).

Despite these explanations, it seems reasonable for clinicians to engage in some level of discussion with psychotherapy patients regarding the nature and extent of treatment, alternatives to treatment, and, when relevant, potential limitations to confidentiality. After all, psychotherapeutic interventions are recommended to patients as treatment options, with particular indications, benefits, and alternatives, and they come with significant personal costs (emotional and financial) and a variety of potential adverse consequences (negative transference reactions, regression, depression, etc.). Therefore, the spirit of the informed consent doctrine, which promotes patient autonomy, would seem to be applicable here.

CONCLUSION

The doctrines of informed consent and competence arise from the ethical and legal principles of respect for patient autonomy balanced with beneficence. Clinically, the doctrines foster collaboration and a therapeutic alliance between psychiatrist and patient. Though questions remain about specific definitions and applications of some of the core principles of the informed consent doctrine, it behooves psychiatrists to become familiar with its theoretical underpinnings, which inform society's goals for maintaining and refining an appropriate system of informed consent.

KEY SUMMARY POINTS

- The three fundamental components of informed consent are information (disclosure), voluntariness, and competence.
- The professional standard or reasonable medical practitioner standard of informed consent limits the amount of information a physician is required to disclose to a patient to that which a reasonable medical practitioner would disclose under similar medical circumstances.
- The reasonable person standard of informed consent requires that a physician disclose information that a typical patient would need to know or consider material to the medical decision at hand.
- The four fundamental standards for determining competence in decision making, in order of increasing capacity required, are (1) communication of a choice, (2) understanding relevant information provided, (3) appreciation of the situation and its consequences, and (4) rational decision making.
- Incompetence is a legal determination and refers to a court's adjudication; incapacity refers to a clinician-determined functional inability.
- Exceptions to the requirement of informed consent are (1) incompetence; (2) emergency medical situations; (3) patient waivers; (4) therapeutic privilege; and (5) involuntary treatment based on statutory, state-specific provisions.

Hospitalization: Voluntary and involuntary

JOSEPH R. SIMPSON AND VINCENZO CARANNANTE

INTRODUCTION

Psychiatry is a rarity among the medical specialties, in that therapeutic interventions such as hospitalization and the administration of medications can, under certain circumstances, be provided to patients against their will and over their objection. (The ability of physicians in the field of public health to confine and treat patients with certain communicable diseases such as tuberculosis is perhaps the only analogue in another medical specialty.) Finding the balance between honoring the rights of the individual citizen to liberty and freedom, and protecting the citizen's own safety and the safety of others, is the challenge faced by any system that allows for involuntary psychiatric confinement and treatment. To understand the issues at stake, it is useful to begin by examining the fundamental concepts by which society, through its government, claims the authority to place a person in a psychiatric hospital.

THE LEGAL FOUNDATIONS OF CIVIL COMMITMENTS

In the United States, forcing someone to enter a facility to undergo treatment is considered a relatively significant curtailment of his or her rights. Each state has its own laws with respect to civil commitment. However, in all cases, a state's right to enact civil commitment laws is derived from two basic legal doctrines: *parens patriae* and police power. *Parens patriae* is the legal doctrine whereby the state acts as the metaphorical parent of its constituents and has the duty and right to act on behalf of or in the best interests of those who do not have the capacity to take actions in their own best interests as a result of age, illness, or other infirmity. A state's "police power" derives from the government's interest to protect its citizens from others and to maintain order in the interest of public safety. Traditional commitment statutes generally attempt to capture the essence of these two powers and are used for those with mental illness who are a danger to themselves, others, or both (Feuerstein et al. 2005).

The history of psychiatric hospitalization in America dates back to the 1750s. Pennsylvania Hospital was opened in Philadelphia in 1752 and featured a dedicated unit for mentally ill patients. In 1773, the Eastern State Hospital in Williamsburg, Virginia, was founded for housing people who were then commonly referred to as "lunatics." New York Hospital, founded in 1791, opened a separate building designated "Lunatic Asylum" in 1808 (Shorter 1997). Several other dedicated hospitals or asylums were started along the Eastern Seaboard in the early nineteenth century, including the Friends Asylum in Frankford, Pennsylvania; the Bloomingdale Asylum in New York; the McLean Asylum in Charlestown, Massachusetts; and the Hartford Retreat (later, The Institute of Living), in Hartford, Connecticut. By 1861, there were 48 asylums in the United States, with a total census of 8500 patients (Katz 1989).

This relatively small number of patients reflects the fact that in the eighteenth and nineteenth centuries, most patients with mental illness did not find their way to asylums. Rather, they were cared for by family members at home or were placed in almshouses or jails. In the 1840s and 1850s, the reformer Dorothea Dix exposed the deplorable conditions endured by many such patients. Her work culminated in the founding of numerous new mental hospitals; 20 states improved their capability of caring for the mentally ill by either building or enlarging their mental hospitals (Brakel et al. 1985).

These early institutions were influenced by European innovations in the treatment of mental illness (Shorter 1997). Although humanitarian motives catalyzed the establishment of the asylums, and "moral [French for 'mental'] treatment" was important to psychiatrists of the day, commitment procedures reflected the paternalistic state of medicine at that time. Patients were admitted to and detained at the hospital on the basis of a doctor's judgment regarding their need for treatment. A patient's only means of challenging his or her confinement was the rarely used "writ of habeas corpus" (Gutheil and Appelbaum 2000). There were few laws or regulations governing admission to a mental hospital. Brakel et al. (1985) cite a New York law enacted in

1788 that authorized two or more judges to direct constables to detain and confine persons, who "by lunacy or otherwise, are furiously mad or are so far disordered in their senses that they may be dangerous to be permitted to go abroad." During much of the nineteenth century, commitment "was predicated only on a mentally ill person requiring care…. Admission was made simple, essentially left in the hands of family members and physicians whenever possible. Hospitalizations were involuntary and treatment was coerced, since it was presumed that all mentally ill patients had compromised reason to the extent that they were unable to request (or refuse) care on their own behalf" (Anfang and Appelbaum 2006, 210).

However, by the middle of the nineteenth century, court decisions and legislative changes established some minimal safeguards of the rights of patients and potential patients. In the 1845 case entitled *Matter of Josiah Oakes*, Oakes was confined at Mclean Asylum in Massachusetts. He invoked the common-law right of habeas corpus in order to challenge his detention. The Massachusetts Supreme Court found that the U.S. Constitution prohibited arbitrary detention without adequate justification. The court stated that "the restraint can continue as long as the necessity [for the patient's and others' safety] continues. This is the limitation and the proper limitation." This case represented an early delineation of the proper criteria for involuntary hospitalization and was one of the first to consider commitment for treatment, as opposed to merely as a means of protecting society from a potentially violent patient (Brakel et al. 1985).

In 1860, Mrs. E. P. W. Packard was confined to the Illinois State Hospital on the petition of her husband. An Illinois statute at the time stated, "[m]arried women and infants, who, in the judgment of the medical superintendent are evidently insane and distracted, may be received and detained at the request of the husband…without the evidence of insanity and distraction required in other cases." After her release 3 years later, her efforts were instrumental in the reform of commitment legislation in her state, which passed a law mandating a jury trial in civil commitments (Brakel et al. 1985).

Through the reforms that began in the mid-nineteenth century, the American legal system recognized for the first time the liberty interests of patients in mental hospitals. Over time, concerns about potential abuses of commitment by unscrupulous relatives and/or physicians led to the adoption of procedural safeguards such as judicial hearings and jury trials for commitment, which were imported from the criminal justice system (Anfang and Appelbaum 2006). However, the basis for hospitalization continued to flow from the doctrine of *parens patriae* (i.e., the patient's need for treatment).

Over the first half of the twentieth century, the censuses of state hospitals swelled, reaching a nationwide total of approximately 500,000 patients in the 1950s (Fisher et al. 2001). Beginning in the 1960s, a number of factors converged, setting in motion the process that became known as "deinstitutionalization," which culminated in the virtual emptying of the nation's state hospitals. One of the many factors in this decades-long transformation was a tightening of commitment standards. States responded to the concerns voiced by advocates for civil liberties by revamping their laws, focusing on stricter dangerousness criteria which offered patients even greater procedural protections. The evolution from *parens patriae* to "police power" as the basis for involuntary commitment can be seen in a series of landmark cases and statutes from the 1960s and 1970s.

With this backdrop, states began to shift away from the traditional "need for treatment" standard to a narrower set of circumstances defined by "dangerousness" to self or others (Testa and West 2010). Although self-danger as a basis for commitment was justified by an appeal to *parens patriae* principles, it was limited to more urgent, life-threatening situations. Commitment of those dangerous to others was seen as a pure exercise of the state's police powers. Dangerousness as the sole ground for civil commitment was first adopted by the District of Columbia in 1964 and then by California, the most populous state and frequently a bellwether for the rest of the nation. California's 1969 Lanterman–Petris–Short Act—which only permitted civil commitment of those who were imminently dangerous to themselves or to others, or who were so "gravely disabled" as to be unable to meet their minimal needs for survival (a variant of danger to self)—quickly became a model adopted by many other states. "Need for treatment" was no longer a substantive factor for civil commitment. Court decisions embraced the "dangerousness model" and need for tighter procedural standards, led by a federal district court decision in *Lessard v. Schmidt* (1972). That court criticized earlier vague "need for treatment" statutes, and subsequent decisions in other states endorsed a constitutional rationale for the belief that the state can intervene only when the lives of the patient or others are in danger (Anfang and Appelbaum 2006). One by one, nearly every state revised its commitment laws and followed suit. Eventually, the prevailing standard for civil commitment in the United States required the presence of dangerousness as a result of mental disease (Testa and West 2010).

OTHER LANDMARK CASES AND LEGISLATIVE ENACTMENTS THAT HAVE SHAPED THE CIVIL COMMITMENT LANDSCAPE

Lake v. Cameron

In 1966, the U.S. Court of Appeals for the District of Columbia decided an important legal case that emphasized dangerousness as the key criteria for involuntary hospitalizations. (See *Lake v. Cameron*, 364 F.2d 657, 1966.) Catherine Lake, a woman with mental illness, had been hospitalized against her will at St. Elizabeth's psychiatric hospital for many years, despite not showing any evidence of dangerousness to herself or anyone else. Lake wished to be set free and petitioned the Court of Appeals for her release

(Testa and West 2010; *Lake v. Cameron*, 364 F.2d 657, 1966). The Court ruled that all patients who were not dangerous should not be confined if a less restrictive alternative were available. "To this day, because of this ruling, psychiatrists who complete emergency evaluations are required by law to recommend the least restrictive level of treatment that will meet the needs of non-dangerous psychiatric patients" (Testa and West 2010).

Jackson v. Indiana

Although *Jackson v. Indiana* concerned a criminal matter rather than civil commitment, it is still considered a landmark case in the civil commitment arena. In this case, a trial court committed a deaf-mute defendant to a mental hospital after he was charged with two criminal offenses and was found incompetent to stand trial. (See *Jackson v. Indiana,* 406 U.S. 715, 1972.) The case was eventually appealed to the U.S. Supreme Court, who vacated Jackson's commitment on the grounds that the defendant was denied equal protection and due process, as guaranteed by the Fourteenth Amendment. The Court pointed out:

> Jackson was not afforded any formal commitment proceedings addressed to his ability to function in society, or to society's interest in his restraint, or to the State's ability to aid him in attaining competency through custodial care or compulsory treatment, the ostensible purpose of the commitment. At the least, due process requires that the nature and duration of commitment bear some reasonable relation to the purpose for which the individual is committed. We hold, consequently, that a person charged by a State with a criminal offense who is committed solely on account of his incapacity to proceed to trial cannot be held more than the reasonable period of time necessary to determine whether there is a substantial probability that he will attain that capacity in the foreseeable future. (*Jackson v. Indiana*, 406 U.S. 715, 738–739, 1972)

As a result of this case, many states enacted laws that limit the amount of time a person may be committed on the basis of incompetence to stand trial.

O'Connor v. Donaldson

In *O'Connor v. Donaldson*, the U.S. Supreme Court held that a "State cannot constitutionally confine without more a nondangerous individual who is capable of surviving safely in freedom by himself or with the help of willing and responsible family members or friends" (*O'Connor v. Donaldson*, 422 U.S. 563, 576, 1975). Courts have interpreted this case in two different manners. Namely, either that a finding of dangerousness is constitutionally required to justify involuntary hospitalization (Stromberg, 1982), or that the nondangerous mentally ill cannot constitutionally be confined without the provision of meaningful treatment. The Supreme Court has not provided further clarification of this specific issue and, thus, this has been left to the individual states to resolve.

Addington v. Texas

In *Addington v. Texas*, the U.S. Supreme Court shed light on, and set forth the acceptable evidentiary standards for, commitment proceedings. (See *Addington v. Texas*, 441 U.S. 418, 1979.) After considering the "preponderance of the evidence" (i.e., more likely than not), "proof beyond a reasonable doubt," and "clear and convincing" (an intermediate standard between preponderance and the higher "beyond a reasonable doubt" standard used in criminal cases) evidentiary standards, the Court ruled that the "clear and convincing" standard should be applied to commitment proceedings. The Supreme Court held that applying the "clear and convincing" standard provided an acceptable balance between providing individuals with adequate due process protections and not making it unduly burdensome to have an individual committed.

Parham v. J.R.

In *Parham v. J. R.*, the Supreme Court balanced the protection of the rights of minors undergoing commitment with an endorsement of medical decision making. (See *Parham v. J.R.*, 442 U.S. 584 1979.) In this case, the U.S. Supreme Court held that a postadmission hearing was not necessary to protect a minor's interests. Instead, the justices found that a neutral fact finder, such as a physician, could determine whether or not the commitment was appropriate, after a complete review of the reasons for the minor's hospitalization. The Court preferred this method to full-blown legal proceedings and believed that a traditional medical evaluation was preferable to a more formal adversarial hearing. In fact, the Court found that turning to the judicial system rather than a "trained specialist" on such matters "can turn rational decision making into an unmanageable enterprise." (See *Parham v. J.R.*, 442 U.S. 584, 608, 1979.)

The *Olmstead* case and the Americans with Disabilities Act

The Americans with Disabilities Act (ADA) was signed into law on July 26, 1990, by President George H.W. Bush. The ADA requires that "no qualified individual with a disability shall, by reason of such disability, be excluded from participation in or be denied the benefits of the services, programs, or activities of a public entity, or be subjected to discrimination by any such entity" (42 U.S.C. §12132). Courts and federal agencies that interpret and implement the ADA have repeatedly stated that the ADA requires that

services for persons with disabilities be provided "in the most integrated setting" and that parties "make reasonable modifications in policies, practices, or procedures when the modifications are necessary to avoid discrimination on the basis of disability, unless the public entity can demonstrate that making the modifications would fundamentally alter the nature of the service, program, or activity" (28 C.F.R. §35.130(b)).

The seminal case with respect to the ADA and balancing providing treatment to individuals in the "most integrated setting" with the limitations on a state's resources is *Olmstead v. L.C. by Zimring, 527 U.S. 581* (1999). In *Olmstead,* the U.S. Supreme Court was presented with the case of two women, both of whom had mental illness and developmental disabilities, who were admitted voluntarily to the psychiatric unit in a state-operated hospital. Following their treatment and after their providers concluded that they were ready to be discharged to community-based programs, they continued to be confined to the hospital for several years because of the unavailability of community-based treatment resources. As a result, the two women filed suit under the ADA, so that they could be released from the hospital. In summary, the Court held that public entities, such as state hospitals, must provide community-based services to persons with disabilities when (1) such services are appropriate; (2) the affected persons do not oppose community-based treatment; and (3) community-based services can be reasonably accommodated, taking into account the resources available to the public entity and the needs of others who are receiving disability services from the entity. It is important to note, however, that the Court's ruling came in four separate opinions and, thus, its holding, interpretation, and the implementation thereof are not entirely clear. For example, five of the Supreme Court justices opined that holding a patient for an unreasonable or unnecessary length of time after the person is ready for discharge constitutes discrimination under the ADA. However, one of the justices argued that a program with a waiting list that moves at "a reasonable pace" would be sufficient, and another justice stated that "a state may not be forced to create a community-treatment program where none exists." As Appelbaum (1999) notes, the impact of *Olmstead* remains unclear. Accordingly, while the Court held that individuals have the right to obtain appropriate treatment in the community, the Court seemed reluctant to force states to develop community-based treatment programs.

Zinermon v. Burch

In this case, Darrell Burch, while allegedly psychotic and disoriented, signed forms requesting admission to, and treatment at, a Florida state mental hospital, in apparent compliance with state statutory requirements for "voluntary" admission to such facilities. After his release, he filed suit against his health-care providers for violating his Fourteenth Amendment (i.e., due process) rights. Specifically, he claimed that they violated state law by admitting him as a voluntary patient when they knew or should have known that he was incompetent to give informed consent to his admission and that their failure to initiate Florida's involuntary placement procedure denied him constitutionally guaranteed procedural safeguards. (See *Zinermon v. Burch*, 494 U.S. 113, 1990.) The Court held that the hospital should have allowed the option of voluntary admission only to patients who were competent to consent to such an admission. Though the Court's decision stressed the importance of "voluntariness" for voluntary admissions and held that appropriate procedural safeguards must be in place to protect a patient's liberty interest, it did not specifically set forth what those procedural safeguards need to be.

RECENT DEVELOPMENTS

The proverbial pendulum has swung back somewhat from the strict dangerousness standards of 30 to 40 years ago. Families of patients with mental illness objected to commitment criteria that made it exceedingly difficult for their loved ones to receive treatment (Dunham 1985). For example, the growth of the homeless population in recent decades is considered by many to have been an unintended consequence of the high threshold for involuntary admission in most states' commitment laws. In Washington State, a highly publicized double murder by a man who had been denied voluntary admission to a state hospital just hours earlier led to calls to change the state's commitment scheme (Durham and LaFond 1985). Washington had passed one of the most narrow commitment statutes in the country in 1973. In 1979 it was significantly relaxed to allow for the involuntary hospitalization of anyone who exhibited a severe deterioration in his or her condition (Durham and LaFond, 1985, 1988). Similar revisions followed in other states. A number of states have expanded their dangerousness criteria by eliminating the requirement for evidence of a specific overt act indicating dangerousness or the requirement that the patient poses a risk of imminent danger. In many states, revised commitment criteria now allow for the involuntary hospitalization of patients who would suffer significant deterioration in their condition if not imminently treated.

The controversies surrounding involuntary psychiatric treatment have by no means subsided. In the past 15 years, a number of mass shootings, many of them committed by people with known or suspected mental disorders, have sparked re-examination of our nation's mental health system, including the laws governing commitment. Many of these high-profile tragedies took place at schools or colleges or involved students as victims. Examples include Columbine High School in Littleton, Colorado, in 1999; Virginia Polytechnic Institute and State University (Virginia Tech) in 2007; Sandy Hook Elementary School in Newtown, Connecticut, in 2012; and a neighborhood in Santa Barbara, California, frequented by college students (Isla Vista) in 2014. Others occurred at public gathering places, including a political event in Tucson, Arizona, in

2011 and a movie premiere in Aurora, Colorado, in 2012. Some of the perpetrators had been evaluated previously by psychiatrists. In the incident at Virginia Tech, the gunman had been psychiatrically hospitalized on an emergency basis and had subsequently been ordered by the court to attend outpatient treatment.

Although mass killings by people with mental illness are extremely rare and account for a miniscule percentage of the nation's homicides, their devastating collective impact, and the possibility of preventing them through early detection and treatment, understandably have led to suggestions that current involuntary commitment standards are too restrictive, causing some people with mental illness to "fall through the cracks" (Neary 2014).

PSYCHIATRIC HOSPITALIZATION: LAWS, PROCESSES, AND PROCEDURES

The specific criteria, procedures, and legal standards pertaining to psychiatric hospitalization are determined by the laws of the state or equivalent jurisdiction (e.g., District of Columbia, Puerto Rico) where the hospital is located. However, the outlines of the system governing hospitalization are broadly similar in most jurisdictions.

Involuntary hospitalization

In most states there are two mechanisms for hospitalizing a patient who is not willing to enter on a voluntary basis. Short-term hospitalization can be accomplished via an emergency certification, typically completed by a physician or other qualified professional, such as a clinical psychologist or psychiatric nurse. Emergency certification is not reviewed by any court or other entity prior to the patient's admission. Emergency detentions are always of limited duration, generally on the order of 2 to 5 days, although the specific length varies by jurisdiction, as does the question of whether weekends or holidays count toward the detention time. At the conclusion of the time allotted for emergency certification, one of three things happens: the patient is released; he or she signs in as a voluntary patient; or the hospital seeks a formal commitment.

A formal commitment can be sought on an outpatient, a voluntary inpatient, or a patient who has been detained via emergency certification. The patient is entitled to due process protections, including the right to representation, a hearing, and an appeal. Again, the specific legal standards and procedures followed vary somewhat by jurisdiction, as does the maximum duration of the commitment. Typical initial formal commitments last on the order of 14 days. For more severely mentally ill patients, longer-term commitment (e.g., placement on guardianship or conservatorship for up to a year) can be sought either at the outset or the conclusion of one or more shorter commitments. In some jurisdictions, the initial hearing on commitment is performed at the hospital, with a neutral referee (appointed by the county) and a patient advocate (also employed by the county) assigned to argue the patient's case for release. Initial hearings in some jurisdictions, as well as appeals of initial determinations (and when longer periods of commitment are sought) are conducted before a judge, with many or all of the trappings of a civil proceeding present. These may include attorneys for both parties, a transcript generated by a court reporter, and proceedings subject to the rules of evidence.

Voluntary hospitalization

In almost every state, a voluntary psychiatric admission is treated differently than a standard medical admission. Most state statutes allow for the hospital to continue to detain a voluntary patient for a certain amount of time after they request to be discharged (Garakani et al. 2014). Unlike the case for patients in medical units, where obtaining a discharge against medical advice (AMA) is typically a relatively simple matter of signing a waiver, gathering one's belongings, and walking out, a voluntary psychiatric patient must notify hospital staff of their request for discharge. In over 30 states, this must be done in writing. The hospital treatment team is then allowed to continue the hospitalization for a period ranging from 4 hours up to 5 days, depending on the state; in some jurisdictions, only business or court days are counted. In some states, the continuation of the admission is contingent on the hospital's application for an involuntary commitment. In others, this is not required. Garakani et al. (2014) have pointed out the need to provide a truly informed consent process for patients at the time of their admission, particularly given the potential for delay in discharge after the patient's request, as well as the potential for conversion of the stay to involuntary status.

SUMMARY KEY POINTS

- Psychiatry is rare among the medical specialties in its ability to hospitalize patients and treat them against their will.
- The legal regulation of hospital psychiatry has evolved from a highly paternalistic, physician-centered model to a system that incorporates a variety of due process protections in an effort to balance the liberty interests of the patient with the safety interest of the patient and the community.
- Procedures for involuntary hospitalization and medication treatment are governed by statute and case law in all jurisdictions.
- In nearly all states, procedures for voluntary admission to and discharge from a psychiatric hospital are distinct from those that apply to admission to and discharge from a medical hospital.

Assisted outpatient treatment and outpatient commitment

GARY TSAI AND CAMERON QUANBECK

INTRODUCTION

Although civil commitment is most often thought of as an inpatient intervention, outpatient commitment (OPC), also known as assisted outpatient treatment (AOT), is another form of civil commitment that mandates adherence to mental health treatment in the community. The common goal of this intervention is to prevent relapse, hospital and criminal justice recidivism, homelessness, and other poor outcomes related to lack of treatment. Court-ordered outpatient psychiatric care is among the most contested and misunderstood issues in mental health law (Brooks 2007, 219; Dale 2010, 271). Yet, given an increasing awareness of the limitations of current mental health-care delivery, there has been a growing interest in exploring its use as a tool to improve treatment adherence in the least restrictive setting possible.

Since the onset of deinstitutionalization in the 1950s, when there were over 558,000 psychiatric hospital beds nationwide, there has been a greater than 90% reduction in available beds, according to the National Association of State Mental Health Program Directors. As of 2010, there are now less than 45,000 psychiatric beds nationwide (Torrey et al. 2012, 5). The reasons for this shift in care were multifactorial, including poor treatment and conditions in mental asylums, the emergence of effective antipsychotic medications, budgetary concerns, and concerns about the *parens patriae* aspect of commitment.

Though the goal of transitioning the care of former mental asylum residents to less restrictive settings such as community mental health clinics was noble, necessary resources to provide treatment in the community never fully materialized (Goldman et al. 1983). Additionally, the expectation that individuals released from psychiatric hospitals would voluntarily seek treatment in the community was overly optimistic for a variety of reasons, including a lack of community resources and the now well-established finding that a significant proportion of persons with serious mental illness lack insight into their psychiatric condition (Husted 1999, 33). Research has demonstrated that a significant percentage of patients (40%–50%) with serious mental illnesses suffer from deficits in insight. Those with impairments in insight have difficulty realizing that (1) they are suffering from psychiatric illness; (2) the symptoms they are experiencing (e.g., delusions, hallucinations, mania) are part of the mental illness; and (3) they likely would benefit from psychiatric treatment (Pini et al. 2001, 124; Dell'Osso et al. 2002, 315; Pini et al. 2003, 355; Cairns et al. 2005, 384). The neurological term for this phenomenon is anosognosia. Advanced neuroimaging techniques, including functional magnetic resonance imaging (Cooke et al. 2008, 40; Bedford et al. 2012, 106; van Der Meer et al. 2013, 1288) and positron emission tomography (Faget-Agius et al. 2012, 297), demonstrate that individuals with poor insight have dysfunctional neuronal circuits predominantly involving the frontal and parietal lobes.

The result of this has been that many individuals with impaired insight—particularly those with more serious mental illnesses, such as psychotic conditions—have had difficulty accessing care in either community mental health centers or inpatient facilities, and have ended up cycling between the criminal justice system, hospitals, and homelessness. Researchers have noted that the large numbers of homeless individuals who are mentally ill suggest that current outpatient mental health services are not meeting the needs of this group (McNiel and Binder 2005, 699). At any given point in time, approximately 40%–50% of cases of serious mental illness in the United States are untreated (Regier et al. 1993, 85; Kessler et al. 2001, 988; Wang et al. 2005, 629; Olfson et al. 2010, 831).

As psychiatric hospital beds have become scarce, there has been increased pressure on public mental health systems to employ more effective interventions in the ambulatory setting. At the same time, it has become clear that a certain subset of individuals with serious mental illness

either cannot or will not adhere to traditional outpatient models of care. As a result, policymakers are discussing how best to engage this population in treatment. These discussions have included the merits of OPC/AOT, including the issues involving legality, eligibility criteria, and its current evidence base (in terms of effectiveness and cost savings) (Swartz et al. 1999, 1968; Appelbaum 2001, 347; Schopp 2003, 33; Swanson et al. 2013, 1423).

HISTORY AND LEGAL CONSIDERATIONS

In the 1960s, a greater emphasis on safeguarding civil liberties led to decreasing public support for the state's commitment authority. Previously, state hospitals employed a conditional release procedure whereby patients who were deemed ready for a trial release from the hospital were given a pass to leave the premises prior to their formal discharge (Miller 1987). However, if clinicians made the determination that patients needed to return to the hospital, superintendents had the authority to recommit these individuals to the state hospital.

Due process reforms in the 1970s led to the 1975 U.S. Supreme Court landmark decision *O'Connor v. Donaldson*, in which inpatient commitment was restricted to individuals who were found to be both dangerous and mentally ill. Civil commitment standards essentially were changed from a "need-for-treatment" to "imminent dangerousness," and many states subsequently tightened their inpatient commitment criteria in response to this landmark ruling. Following these modifications, some mental health providers noted that the combination of narrowed treatment criteria and underfunded community mental health services was contributing to "revolving door" recidivism (King 1995, 254). In instances such as these, chronically ill people who generally do not seek treatment voluntarily are only treated when allowable according to legal commitment standards. However, many are stabilized only to the point where they no longer meet the inpatient commitment standards and are subsequently released, only to resume this cycle by ceasing to take their medications once they leave the structured confines of a hospital (Appelbaum 2001, 348; Kress 2006, 573).

In the 1980s, there was a push to expand the state's role in the management of the chronically mentally ill and to once again lower commitment standards. In 1983, North Carolina became the first state to enact preventive outpatient commitment statutes, in which traditional OPC standards were broadened to include individuals who did not meet inpatient commitment criteria (Stefan 1987, 288). The rationale for this was to intervene in the lives of individuals with chronic recidivism prior to their becoming irretrievably ensnared in the aforementioned "revolving door." Preventive outpatient commitment laws have since expanded to include 45 states in the United States. As of the writing of this chapter, the only states without preventive outpatient commitment laws were Connecticut, Maryland, Massachusetts, New Mexico, and Tennessee.

OUTPATIENT COMMITMENT: RATIONALE AND CRITICISMS

Coercion in psychiatric care remains a controversial tactic, and the debate regarding the practice has shifted from the inpatient to outpatient setting, as the majority of mental health-care delivery has transitioned from institutions to the community (Munetz et al. 2003, 173). Courts have consistently upheld the right of individuals to make lawful decisions about most aspects of their lives, free from intrusion. The legal doctrine of informed consent outlines that individuals should be able to express and understand the complexities of a given choice and rationally manipulate the components of that decision in order to comprehend and compare alternative options (Appelbaum et al. 1987, 3). However, the issue of fully informed consent in psychiatric practice is complex, particularly given deficits in executive functioning and reasoning that frequently accompany serious mental illness.

The MacArthur Foundation competence studies divided competence into four different variables: choice, understanding, reasoning, and appreciation (Appelbaum and Grisso 1995, 105; Grisso and Appelbaum 1995a, 1034, 1995b, 149). These studies found that as a whole, psychiatrically hospitalized patients were at greater risk for deficits in decision making when compared to medically hospitalized patients, but also found that these impairments were, at times, temporary and improved with treatment. Although some individuals regain their decision-making capacity after successful treatment (Turkington et al. 2002, 523; Rittmannsberger et al. 2004, 174), a portion of individuals persistently lacks capacity despite treatment.

Researchers have found that over half of individuals with schizophrenia experienced deficits in the understanding, reasoning, and appreciation aspects of these standards, indicating impaired decision-making capacity (Grisso et al. 1995, 127). Given the growing research suggesting a neurobiological basis for this lack of self-awareness (Lysaker et al. 1997, 297; Keefe 1998, Young et al. 1998, 44; Mohamed et al. 1999, 525; Flashman et al. 2000, 1167), which most commonly implicates dysfunctional circuits in the right parietal and frontal lobes (which affect executive functioning) (Raffard et al. 2008a, 511), the pathologic biology of schizophrenia may prevent certain individuals with this condition from being able to make informed decisions. Research has supported the notion that insight is complex and exists in varying degrees, from complete denial of diagnosis, to vague recognition, to full appreciation of illness (Marková and Berrios 1995, 367).

Critiques of coercive treatment in general, and OPC in particular, typically involve several key issues. One is a "rights-based" argument, founded on the principle of self-determination and the view that involuntary treatment is a violation of one's civil liberties (Hoge and Grottole 2000, 165; Lamb and Weinberger 2013, 290). Those espousing this perspective frequently contend that seriously mentally ill individuals should have the freedom to decide whether or not to

accept treatment unless they are legally deemed incompetent or pose a clear danger to themselves or others (Schopp 2003, 33), and that coercive treatment will discourage individuals from seeking mental health care voluntarily in the future (Allen and Smith 2001, 342). Because the legal definition of competence differs from the clinical definition of capacity, there are important clinical implications to this more narrowly defined interpretation of the circumstances under which involuntary psychiatric care should be provided.

Proponents of OPC often opine that self-determination in the context of impaired decision-making capacity is arguably impossible, and that these instances—a relatively common scenario in acute psychiatric settings—highlight the need for court-ordered outpatient treatment and the fine line between patient autonomy and beneficence (Torrey and Zdanowicz 2001, 337). In light of a growing body of evidence that earlier diagnosis and treatment of psychosis lead to improved prognosis (Bottlender et al. 2003, 37; Craig et al. 2004, 1067; Perkins et al. 2005, 1798; Malla et al. 2005, 881; Raffard et al. 2008b, 597), allowing psychiatric patients to refuse care in these scenarios can "empower" the symptoms of the condition rather than empowering the patient. Indeed, the association between lack of insight and schizophrenia has been linked to medication nonadherence, severe positive psychotic symptoms, psychiatric hospitalizations, comorbid depression, poor occupational functioning, homelessness, substance use, and poorer overall prognosis (Lysaker et al. 1994, 307, 2002, 142; Smith et al. 1999, 102; Löffler et al. 2003, 105; Mintz et al. 2003, 75; Rittmannsberger et al. 2004, 174; Olfson et al. 2006, 205). Ironically, some observers have noted that mandated outpatient treatment may actually lead to decreased involuntary care by decreasing the need for other mandatory interventions that are provided in more restrictive settings (Zanni and Stavis 2007, 31; Link et al. 2011, 504).

Interestingly, studies that have focused on perceived coercion among the consumers who are directly impacted by mandated outpatient treatment orders have been mixed. A self-report study analyzing perceived coercion with OPC found that persons subjected to mandated treatment reported higher levels of perceived coercion, which was directly proportional to the duration of their mandate (Swartz et al. 2002, 214). This study also suggested that perceived coercion was independently associated with several clinical characteristics, most notably severe symptoms, anosognosia, and substance use. Conversely, results of interviews with consumers with schizophrenia or related disorders indicate that 62% regarded mandated outpatient care as effective, and 55% reported that they felt such interventions were fair (Swartz et al. 2004, 780). Overall, these individuals tended to believe that OPC was beneficial and in their best interests, particularly participants who were less symptomatic, possessed better insight, and adopted a more biopsychosocial view of their own condition. Other studies have yielded similar results when psychiatric patients who received involuntary treatment were asked about their views on their coerced treatment, with a majority indicating that in retrospect, they agreed such treatment was in their best interests (Schwartz et al. 1988, 1049; Greenberg et al. 1996, 513).

A similar analysis was performed comparing the views of coercion in OPC among four stakeholder groups: consumers with schizophrenia and related disorders, their family members, treating clinicians, and members of the general public (Swartz et al. 2003, 1139). In each stakeholder group, avoiding inpatient hospitalization and interpersonal violence, and maintaining good interpersonal relationships were prioritized over concern about coercion with OPC. The results of this study suggest that the perceived coercion of mandated outpatient treatment may be a more tolerable alternative than other negative outcomes.

Resource-based arguments also are cited both in support of and against mandated outpatient treatment. Opponents of OPC commonly hold a utilitarian perspective that investing resources into services that provide the greatest good for the greatest number of people is the preferred course of action. As a result, they espouse ensuring that voluntary mental health services are available to the masses before targeting a minority of those with severe mental illness with involuntary interventions. In this case, the specific rationale is often that removing barriers to voluntary mental health services would accomplish the same objectives as OPC and would make expanding involuntary interventions unnecessary (Brown 2003, 7; Winick 2003, 107). In one California study, an infusion of resources into the public mental health system, which contributed to an improvement in access and quality of mental health care, was followed by a decrease in the number of petitions for involuntary 14-day holds, though the number of petitions for involuntary 72-hour holds was unchanged (Bruckner et al. 2010, 1008). There is also concern that investing resources in OPC will result in a reduction in voluntary services, though some research challenges this belief. New York State's AOT implementation ultimately led to greater access to intensive services for both voluntary and involuntary patients (Swanson et al. 2010, 992).

Conversely, the growing evidence supporting the neurobiological basis of anosognosia has led to recognition of an expanding chasm in access to care. That is, those who are more psychiatrically stable are able to accept care voluntarily, while those who are unable to recognize their illness are refusing voluntary care and placing themselves at greater risk of succumbing to the various negative outcomes of serious mental illness. Thus, the resource-based argument commonly cited in support of OPC is that the high costs of recidivism for both the mental health and criminal justice systems (Swanson et al. 2013, 1430) are ultimately unsustainable and inequitable, and that devoting resources to the minority of high-utilizing, recidivist patients may be a more appropriate and efficient allocation of limited mental health resources.

OUTPATIENT COMMITMENT STATUTES

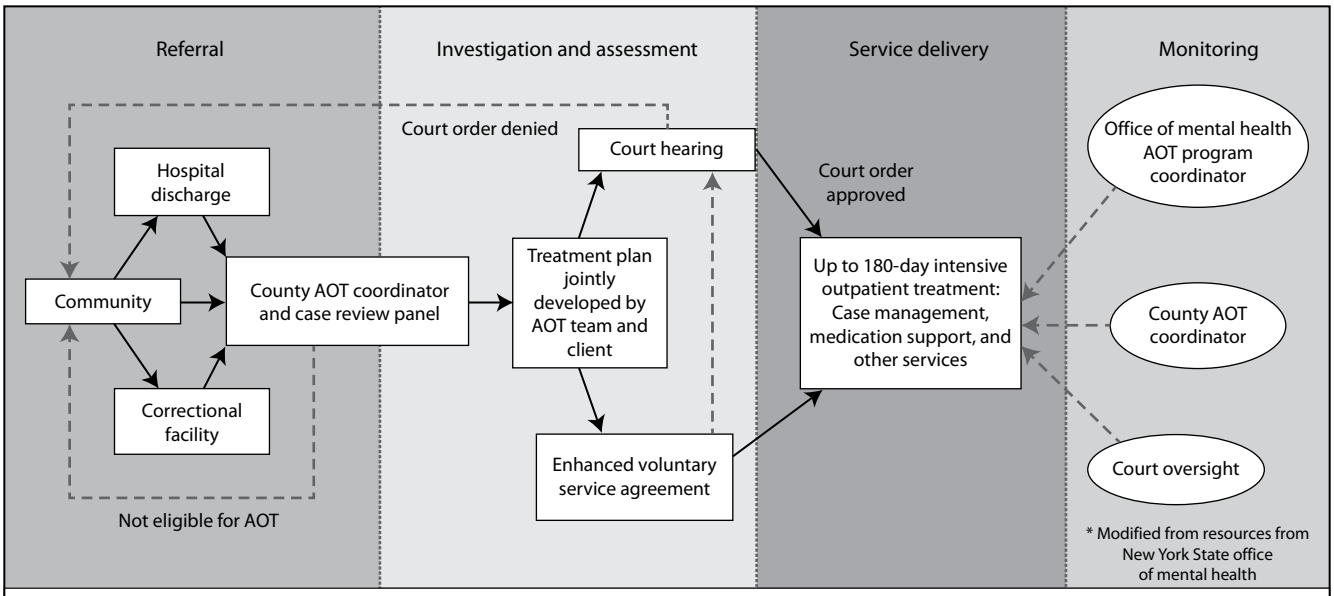
All OPC programs target severely mentally ill adults who have a history of recidivism and refusing voluntary

treatment, and attempt to engage and stabilize this population in the community by providing comprehensive services via a multidisciplinary treatment team. Although a majority of state legislatures have OPC statutes, the eligibility criteria, utilization, and systematic implementation of these programs vary significantly. Some states have OPC statutes with standards written so narrowly that they are unusable and OPC is nonexistent (Stettin et al., 2014, 1). Some experts have observed that there are several challenges to overcome before OPC can be widely and successfully implemented: (1) statutes must be accompanied by sufficient resources to provide the necessary intensive outpatient services, and (2) widespread support is needed among the community mental health providers who will be directly involved in clinical care within these programs (Miller 1988, 99). As mentioned previously OPC/AOT programs' roles within the mental health community continue to be controversial. Additionally, many states that have passed OPC legislation have not provided additional revenue to fund these programs and have not made implementation a statewide requirement, instead allowing local authorities to make decisions about implementation (or lack thereof).

In distinct contrast to comparable programs in other states, New York's is one of the few that allocated sufficient funds for their AOT program (through Kendra's Law). As a result, New York's OPC process is one of the most comprehensive in terms of implementation, infrastructure, and oversight (Swartz 2009, 1) and has served as a model for other states (Petrila and Christy 2008, 21).

As illustrated in Figure 16.1 and described in a report by the New York State Office of Mental Health (Swartz et al. 2009, 5), New York's AOT program consists of four phases: referral, investigation/assessment, service delivery, and monitoring. In the initial phase, referrals from the community or local hospital/correctional facility can be made to the AOT Coordinator, who performs a preliminary investigation to determine if the program's eligibility criteria are met (see bottom of Figure 16.1).

Eligible cases are then transferred to the AOT Case Review Panel for additional vetting in order to assess needs and collaborate with the referred individual in order to devise a treatment plan. Participants may agree to accept services and sign an enhanced voluntary service (EVS) agreement. Within New York, there is procedural variability in that some counties will replace a court order with the EVS, while others require that a court order be filed with the EVS. If a court order is necessary, the AOT team will petition the court to issue a court-ordered treatment plan. This plan consists of intensive, multidisciplinary care, including case management or Assertive Community Treatment (ACT), medication, and housing support, and other court-mandated services to help ensure the individual's stability



Referral
Investigation and assessment
Service delivery
Monitoring
Court order denied
Court hearing
Court order approved
Hospital discharge
Community
County AOT coordinator and case review panel
Treatment plan jointly developed by AOT team and client
Up to 180-day intensive outpatient treatment: Case management, medication support, and other services
Office of mental health AOT program coordinator
County AOT coordinator
Court oversight
Correctional facility
Enhanced voluntary service agreement
Not eligible for AOT
* Modified from resources from New York State office of mental health

New York AOT eligibility criteria (New York Mental Hygiene Law, Section 9.60)

1. At least 18 years old and suffering from mental illness.
2. Clinical determination needs to indicate that they are unlikely to survive safely in the community without supervision.
3. History of lack of compliance with treatment for mental illness that has significantly contributed to at least two hospitalizations or incarcerations within the last 36 months, or one or more acts of serious violent behavior in the last 48 months.
4. Unlikely to voluntarily participate in outpatient treatment that would enable him or her to live safely in the community.
5. Considering treatment history and current behavior, is in need of assisted outpatient treatment in order to prevent a relapse or deterioration which would likely result in serious harm to self/others.
6. Likely to benefit from assisted outpatient treatment.
7. Previously executed health care proxies shall be taken into account by the court in determining the written treatment plan.

Figure 16.1 New York—assisted outpatient treatment process and eligibility criteria.

in the community. Upon issuance, court-ordered treatment plans may be in force up to 6 months and are eligible for renewal for successive periods of up to 1 year.

During the hearing, evidence from the petitioner and patient are presented to establish whether or not there is clear and convincing evidence that the AOT eligibility criteria are met and that the intervention is the least restrictive alternative available to the patient. The hearing process provides an important opportunity for "procedural justice," including a fair and just decision-making process, the active involvement of all participants, and benevolence on the part of authority figures (McKenna et al. 2001, 573). Research has shown that the perception of procedural justice may mitigate feelings of coercion and improve therapeutic outcomes in terms of individuals' enhanced acceptance of and engagement with treatment processes (Tyler 1992, 437; Nicholson et al. 1996, 201; Winick 1997, 30, 2003, 107; Cascardi et al. 2000, 731; Poythress et al. 2002, 529).

When patients under court order do not engage with treatment despite efforts by the treatment team to achieve compliance, the New York AOT statute allows for the patient to be transported to a local evaluating facility for assessment for up to 72 hours in order to determine if the individual meets the criteria for inpatient hospitalization. If the criteria for involuntary hospitalization are not met, the patient must be released immediately. Although this intervention incentivizes treatment compliance to a certain extent, the mechanism for achieving this compliance has been attributed to the power of the court, a term known as "therapeutic jurisprudence" or the "black robe effect." Therapeutic jurisprudence has been described as a therapeutically oriented judicial process whereby the judge plays an active role in leading a team-based approach to the treatment process (Monahan et al. 2001, 1200; Watson et al. 2001, 478). The successes of mental health and drug court models, which have relied on therapeutic jurisprudence to influence treatment compliance, have supported the effectiveness of this judicial leverage. On a "paternalism spectrum," therapeutic jurisprudence seems to lie somewhere between voluntary psychiatric care and conservatorships/guardianships, and is viewed by some as an important tool for encouraging treatment adherence in instances of compromised decision-making capacity (Monahan et al. 2003, 35).

According to a 2009 program evaluation report by the New York State Office of Mental Health (Swartz et al. 2009, 50), the AOT statute's requirements have led to improved access and coordination of services, enhanced accountability in mental health systems, and improved collaboration between the mental health and court systems. In spite of initial concerns that the AOT eligibility criteria may have been overly broad and ensnared those who did not require AOT services, an analysis found that only about 2% of the severely mentally ill service populations in New York were recipients of AOT services. Thus, although OPC orders were applied only in a small fraction of cases, the benefits of implementation extended to voluntary mental health patients by way of the resulting program enhancements required by the AOT program.

CURRENT RESEARCH

The evidence base for OPC and AOT has grown in quantity, quality, and geographic generalizability over the past several decades. As a result, there has been increasing interest and controversy surrounding this intervention. Early studies were largely anecdotal and had mixed results. Even though one of the first studies of court-ordered outpatient treatment found the intervention to be effective at reducing hospital readmissions in North Carolina, and therefore a viable, less restrictive alternative to involuntary hospitalization (Hiday and Goodman 1982, 81), a survey of clinicians' opinions (in a different Congressional district in North Carolina) found that many did not feel it was helpful (Miller and Fiddleman 1984, 147). A study of OPC in Tennessee also demonstrated that although recipients of mandated outpatient treatment showed a reduction in hospital readmission rates, a comparison with control groups revealed that these results were not attributable to the court intervention (Bursten 1986, 1257).

Subsequent research in Washington, DC (Zanni and DeVeau 1986, 941), found decreased rates of hospital readmissions and reduced lengths of stay, with similar results replicated in Ohio (Munetz et al. 1996, 1251) and Arizona (Van Putten et al. 1988, 953). Patients in the Ohio study who received OPC experienced significant reductions in psychiatric emergency room visits, hospitalizations, and lengths of stay, in addition to greater levels of participation in outpatient appointments after their discharge. In the Arizona study, there was also a significant increase in the percentage of patients who voluntarily engaged with their community mental health center 6 months after OPC.

To date, there have been only two randomized controlled trials of outpatient commitment in the United States and one such study in the United Kingdom. A 1994 study evaluated the effectiveness of a 3-year OPC pilot program at Bellevue Hospital in New York City, randomly assigning 142 participants to either a court-ordered treatment group with access to enhanced mental health services or a control group with access only to the enhanced services (Steadman et al. 2001, 330). After analyzing post-discharge follow-up interviews at 1, 5, and 11 months, investigators found no significant differences between the two groups on the major outcome measures of rehospitalizations, arrests, quality of life, symptomatology, treatment nonadherence, and perceived level of coercion. A key limitation of this study was that there was no enforcement of the court order and no procedure in place to respond to nonadherent individuals under court-ordered treatment, which likely diluted the differences between the two groups. Additionally, violent patients were omitted from the study because of ethical concerns, compromising the study's generalizability.

Similar limitations plagued the Oxford Community Treatment Order Evaluation Trial (OCTET), a randomized controlled trial of community treatment orders in the United Kingdom (Burns et al. 2013, 1627). In this analysis, 336 patients were assigned to either the experimental community treatment order (CTO) group or a "Section 17 leave"

group, which served as the control condition. "Section 17 leave" refers to a well-established conditional release practice whereby hospitalized patients are authorized to leave the premises, provided they comply with outpatient treatment. They can be readmitted to the hospital without any additional legal processes should they become nonadherent to treatment in the community. Unlike OPC orders in the United States, which are issued by a court, clinicians issue CTOs in the United Kingdom. Therefore, both groups were required to receive compulsory, intensive supervision in the community, though forced outpatient treatment for patients was not authorized. At 12 months, there were no significant differences in outcomes, which included hospital readmissions, duration of hospitalizations, community stability, and clinical and social functioning.

However, researchers have highlighted important design challenges of the OCTET study (Swanson and Swartz 2014, 808). First, the experimental CTO group was not under court order and therefore avoided the impact of therapeutic jurisprudence and the "black robe effect," which is cited by OPC proponents as an important benefit of mandated outpatient care. Second, although the study has been used to compare voluntary interventions with OPC, the control group also did not receive a truly voluntary intervention, given the coercive influence of conditional release practices. These design limitations limit the generalizability of the OCTET study, and critical questions about the effectiveness of OPC compared to voluntary interventions are not answered.

The North Carolina randomized controlled trial analyzed 331 involuntarily hospitalized patients awaiting discharge, assigning them to either a group that was released to standard case management and outpatient treatment or a group under an outpatient commitment order (Swartz et al. 2001a, 325). Patients in the control group could not be placed under outpatient commitment for a period of 1 year. When the duration of OPC was not taken into account, outcomes for the OPC group did not differ significantly from those for the control group. However, extended mandated outpatient treatment was associated with 57% fewer hospitalizations when compared with the control group's hospitalizations. Individuals in the OPC group also averaged significantly shorter lengths of stay (20 days shorter). Additionally, patients who engaged with three or more outpatient service contacts per month and received sustained OPC were significantly less likely to be violent than those in the control group (24% versus 48%, respectively). Criminal victimization also significantly decreased in the treatment group (24% of the OPC group experienced victimization compared to 42% of the control group). Overall, the authors of this study concluded that a court order was not an adequate substitute for effective treatment, but that mandated outpatient treatment could lead to enhanced outcomes when sustained and combined with intensive outpatient services.

Subsequent outpatient commitment studies replicated many of these positive clinical outcomes, namely decreased psychiatric inpatient admissions and lengths of stay (Rohland et al. 2000, 383; Frank et al. 2005, 867), reduced rates of homelessness (Compton et al. 2003, 27), reduced violence and victimization (Swanson et al. 2000, 327; Appelbaum 2001, 347; Hiday et al. 2002, 1403; Frank et al. 2005, 867), and improved treatment adherence (Swanson et al. 1997, 8; Swartz et al. 2001b, 583). Evidence that mandated outpatient treatment can reduce criminal behaviors (Erickson 2005, 627; Gilbert et al. 2010, 996; Segal 2012, 1454) led the Office of Justice Programs, an agency of the U.S. Department of Justice, to designate AOT "an effective crime prevention intervention" (AOT 2012).

Analyses of Medicaid claims and state reports on 3576 patients involved in New York's AOT program yielded similar results (Swartz et al. 2010, 976). Compared to periods of time prior to the initiation of an AOT court order, AOT participants experienced a 25% reduction in psychiatric hospitalizations and over a 30% decrease in inpatient admissions after the AOT orders were renewed for 6 months. Significant declines in inpatient lengths of stay also were evident, with the average pre-AOT duration of hospital admission lasting approximately 18 days, compared to 11 days during the first 6 months of the court order and 10 days during subsequent months of mandated outpatient care. Greater access to medications and comprehensive mental health services, such as Assertive Community Treatment or intensive case management, also were evident. A number of studies have consistently supported the observation that OPC is most effective when sustained longer than 6 months and combined with intensive community-based services (Swartz et al. 1999, 1973; Swanson et al. 2003, 473; Wagner et al. 2003, 145; Van Dorn et al. 2010, 982).

Although the existing scientific literature suggests that OPC is associated with certain improved treatment outcomes, some have questioned whether these improved outcomes are related to the influences of the court order itself or the intensive outpatient treatment that accompanies OPC. A 2001 RAND meta-analysis found that involuntary OPC can be effective at reducing negative outcomes such as psychiatric relapse, violent behavior, and criminal recidivism among people with severe mental illness, but only when combined with enhanced, community-based mental health services (Ridgely et al. 2001, 98). Consequently, the authors of this study attributed the resulting benefits to enhanced services and monitoring, noting "While there may exist a subgroup of people with severe mental illness for whom a court order acts as leverage to enhance treatment compliance, the best studies suggest that the effectiveness of outpatient commitment is linked to the provision of intensive services. Whether court orders have any effect at all in the absence of intensive treatment is an unanswered question." Critics of the RAND study have noted that its conclusion questioning the benefit of the court order contradicts the authors' acknowledgement that court orders may be beneficial for a select population of individuals.

In summary, the evidence base generally supports the effectiveness of mandated outpatient treatment when appropriately implemented, targeted, and funded. Research has persuasively shown that OPC can lead to improved

treatment outcomes, with success contingent upon the availability of intensive mental health services and the duration of the court order.

COST ANALYSES OF TREATMENT NONADHERENCE AND ASSISTED OUTPATIENT TREATMENT

Given the considerable human, societal, and financial costs of recidivism and untreated serious mental illness (Insel 2008, 663), successful efforts to decrease hospitalizations and criminal justice recidivism can result in significant economic benefits. In a study that quantified the excess annual costs associated with persons with schizophrenia in the United States (Wu et al. 2005, 1122), investigators used administrative claims data for both privately ($N = 1090$) and publicly (Medicaid, $N = 14{,}074$) insured patients. Annual, direct, non-health-care costs were estimated for law enforcement, homeless shelters, and research/training related to schizophrenia and then added to indirect projected costs for unemployment, reduced workplace productivity, premature mortality from suicide, and family caregiving. Overall, the 2002 U.S. cost of schizophrenia was estimated to be $62.7 billion, with $22.7 billion attributable to direct health-care costs, $7.6 billion to direct, non-health-care costs (including $2.64 billion in annual law enforcement costs), and $32.4 billion to indirect costs.

Persons with serious mental illness who do not adhere to their prescribed medication regimens in the community are at high risk of relapse and requiring acute psychiatric care, which is the most expensive type of mental health treatment. Currently, the average length of stay for acute psychiatric hospitalization is 5–6 days (Glick et al. 2011, 207). However, this length of stay is often inadequate to stabilize psychiatric crises and can lead to readmission (Boaz et al. 2013, 1225). Given the scarcity of psychiatric hospital beds across the nation, adherence to psychotropic medications is critical in preventing rehospitalization. Studies measuring adherence in those with serious mental illness indicate that this phenomenon is common. In a study of Medicaid beneficiaries with schizophrenia, pharmacy records demonstrated that 40% of patients were either nonadherent or partially adherent to their medication regimens. Those who were nonadherent incurred significantly more hospital costs than those who were adherent (Gilmer et al. 2004, 694).

A similar study of patients with schizophrenia in California found that even small gaps in medication adherence (i.e., 1–10 days) increased risk of hospitalization (odds ratio 1.98), and larger gaps (11–30 days and beyond) increased hospitalization risk further (odds ratio 2.81 and 3.96, respectively). In a retrospective analysis of 1500 individuals with schizophrenia who had been prescribed antipsychotics and then were followed for 12 months after the initial prescribing, those with a "medication gap" of greater than 30 days were 4.7 times more likely to be hospitalized than those who had a medication gap of 0–10 days. The risk of hospitalization for patients with a "medication possession ratio" (MPR) (i.e., percentage of days with prescription antipsychotic available for consumption) of less than 70% were significantly more likely to be hospitalized than those who obtained medication more consistently, with the risk of hospitalization decreasing 16.9% for every 10% increase in "medication possession" (Kozma and Weiden 2009, 36).

A study examining rehospitalization costs for Medicaid recipients who relapse because of nonadherence estimated annual costs to be $1.479 billion (Sun et al. 2007, 2305). Even small increases in medication continuity could result in significant cost savings in inpatient care costs for the national Medicaid system (Marcus and Olfson 2008, 177). A 3-year study of 1906 persons with schizophrenia found that antipsychotic nonadherence was associated with poorer functional outcomes and greater risks of hospitalization, use of emergency services, arrests, violence, victimization, and drug- and alcohol-related problems (Ascher-Svanum et al. 2006, 453).

Research has demonstrated that psychotropic nonadherence has similar deleterious effects for those with bipolar disorder. In a study of individuals with bipolar disorder with predominantly manic or mixed symptoms, a higher MPR significantly reduced total mental health expenditures, with a reduction in expenditure of $123 to $439 per one-point increase in MPR (Gianfrancesco et al. 2008, 1358). A study of patients with bipolar disorder discharged to the community found that those with an MPR of at least 0.75 had significantly lower risks of hospitalization (Hassan and Lage 2009, 358), and persons with bipolar disorder with MPRs of 0.8 and 0.9 were able to remain in the community and avoid rehospitalization and emergency services (Lage and Hassan 2009, 4). Irregular medication use is one of the strongest predictors of hospital use and cost among those with serious mental illness, and leads to hospital costs four times greater for these individuals than for those who take psychotropic medications regularly (Svarstad et al. 2001, 810). Clearly, the cost savings potential for interventions that improve treatment compliance and decrease recidivism are impressive.

In response to increasing interest and questions from policymakers, perhaps as a result of growing evidence of the merits of mandated outpatient treatment, researchers recently have attempted to evaluate the cost-effectiveness of this intervention. Investigators conducted a comprehensive analysis of the net costs of AOT programs in New York City and five surrounding counties by reviewing 36 months of observational data for 634 AOT participants and 255 recipients of voluntary intensive outpatient treatment (Swanson et al. 2013, 1423). Costs for the program were calculated from claims data that focused primarily on criminal justice and legal spending, expenditures for mental health and other medical treatment, and program administration costs. During the first 12 months after mandated outpatient treatment was initiated, hospitalizations decreased markedly, with modest declines sustained through the subsequent 12 months after the program's initiation. Utilization of psychiatric emergency and crisis services, and criminal justice involvement were also reduced. As costs for hospitalizations

and other encounters declined, spending on outpatient care increased. When the entire sample was analyzed, total net costs declined by approximately 45% in the first year after the initiation of court-ordered treatment, followed by an additional 13% reduction in the second year. The data suggested that the reductions in net costs were attributable to shifting patterns of service provision, from repeated inpatient contacts to regular outpatient encounters. Based on these results, the authors concluded that states can reduce overall services costs for individuals with severe mental illness, provided that the geographic area was willing and able to invest the necessary resources to adequately fund an OPC program and intensive outpatient services.

These findings were corroborated in a cost-analysis study conducted in North Carolina (Swartz and Swanson 2013, 7). In this study, net costs were calculated from data from a prior randomized controlled trial by the same researchers (Swartz et al. 2001a, 325). Updated service unit prices for inpatient and outpatient services, arrests and days of incarceration, civil court costs, and administrative overhead were included in the analysis. Although total annual costs were approximately $3000 higher for the OPC group than the control group ($46,510 versus $43,516, respectively), when mandated outpatient treatment orders were extended for over 6 months, the total costs decreased by about 40% (or $17,594). These results suggest that the implementation of OPC programs could be cost-neutral if the funding and infrastructure for intensive outpatient services was available, and that this intervention could lead to cost savings if court orders for community-based services were extended beyond 6 months.

Finally, comparable outcomes were found in an AOT program in Nevada County, California, a small, rural community with a population of 100,000 (Tsai 2012, 16). When hospitalizations and incarcerations were compared in the same population both pre- and post-AOT over a period of 31 months, court-ordered participants experienced significant reductions in psychiatric hospitalization days (61% decrease) and incarceration days (97% decrease). As a result, Nevada County realized a net savings of 45% after implementing their OPC program, returning $1.81 for every $1 invested into the program.

SUMMARY

Clinical and legal interventions have been proposed to address the complex challenge of engaging in treatment individuals with serious mental illness and a history of recidivism. Given the poor outcomes associated with lack of treatment and the impaired decision-making capacity that impacts some people with serious mental illness, outpatient commitment has been suggested as a reasonable option to provide necessary care in the least restrictive setting possible.

However, opponents of court-ordered outpatient treatment have expressed concern about the consequences of its widespread implementation. Research has provided some clarity about the concerns, benefits, and economic considerations of OPC. Evidence from a variety of settings, including New York, North Carolina, and California generally has supported the notion that this intervention is effective when appropriately funded, implemented, and applied. Additionally, New York's AOT program was found to improve the mental health system as a whole, both for AOT participants and for voluntary recipients of services, presumably because of improved accountability and collaboration between state agencies, and the enhanced services that are required by mandated outpatient treatment. Although the limitations of mental health systems are multifaceted, and outpatient commitment is not a panacea for these shortcomings, AOT has proved to be a useful tool for engaging a certain subset of people with serious mental illness.

SUMMARY KEY POINTS

- Outpatient commitment, also known as assisted outpatient treatment, involves court-ordered, intensive, community-based mental health services that target individuals with a history of recidivism and treatment nonadherence.
- The intervention is controversial. Opponents cite concerns about undermining self-determination, damaging therapeutic relationships (and subsequent decreased voluntary engagement in treatment in the future), and siphoning resources away from voluntary services. Proponents note that some individuals who lack insight into their mental illness lack the capacity to accept care voluntarily and require involuntary interventions to prevent poor outcomes. They also note that OPC is community based and a less restrictive alternative than other potential interventions or outcomes (e.g., hospitalization, incarceration).
- A balanced assessment of the evidence generally supports the notion that OPC is effective and that it is associated with reduced hospitalizations, reduced criminalization and victimization, improved engagement with outpatient treatment, and cost savings from reduced recidivism.
- Appropriate funding, the availability of intensive community-based services, and the duration of the court order are factors influencing whether OPC can be implemented effectively.

The right to treatment

JEFFREY L. GELLER

INTRODUCTION

The right to treatment was born in the early 1960s, its progenitor the decades of parlous neglect of patients in America's public psychiatric institutions through the mid-twentieth century. Kenneth Appel, MD, chairperson of the mental hospitals committee of the Group for the Advancement of Psychiatry, proclaimed in 1947, "Automobiles get better attention than most mental patients today. The grass surrounding the state hospitals receives more care and consideration than the patients inside" (Deutsch 1948, 98). In his 1958 presidential address to the American Psychiatric Association (APA), Harry Solomon indicated that "the large mental hospital is antiquated, outmoded, and rapidly becoming obsolete. We can build them but we cannot staff them…they are bankrupt beyond remedy" (Solomon 1958, 7).

Much of the right-to-treatment litigation has focused on establishing standards of care and concomitant staffing patterns. In the 1940s, the APA maintained that there should be no less than one psychiatrist for every 150 hospitalized patients, one graduate nurse for every 40 patients, and one attendant for every 8 patients, but no state hospital of the day met all the APA's standards (Deutsch 1948).

The history of the right to treatment is that of a moral position casting about for legal grounding. The right to treatment has been variously based on the Eighth Amendment (cruel and unusual punishment), the Fourteenth Amendment (both the Due Process and the Equal Protection Clauses), the "quid pro quo" rationale (i.e., treatment is due to civilly committed patients in exchange for enforced confinement), and the "least restrictive alternative" doctrine ("deprivations of liberty solely because of dangers to ill persons themselves should not go beyond what is necessary for their protection") (*Lake v. Cameron* 1966, 660). Further, courts have struggled with clearly defining *treatment,* differentiating between *treatment* and *habilitation*, and distinguishing between the rights and needs of persons with mental illness and those with developmental disabilities.

INSTITUTIONAL TREATMENT

The early years: 1960–1974

The right to treatment was articulated initially by Morton Birnbaum, a lawyer and physician, who argued in 1960:

> If the right to treatment were to be recognized, our substantive constitutional law would then include the concepts that if a person is involuntarily institutionalized in a mental institution because he is sufficiently mentally ill to require institutionalization for care and treatment, he needs, and is entitled to, adequate medical treatment; that an institution that involuntarily institutionalizes the mentally ill without giving them adequate medical treatment for their mental illness is a mental prison; and that substantive due process of law does not allow a mentally ill person who has committed no crime to be deprived of his liberty by indefinitely institutionalizing him in a mental prison. (Birnbaum 1960, 503)

The first tests of Birnbaum's theory were in criminal committees. In *Rouse v. Cameron* (1966), Judge Bazelon found that a District of Columbia statute mandated treatment for a patient committed after a finding of not guilty by reason of insanity. Judge Bazelon postulated, however, that there could be constitutional violations in confinement without treatment, noting the Eighth and Fourteenth Amendments. He further remarked that the "hospital need not show that the treatment will cure or improve him, but only that there is a bona fide effort to do so" (*Rouse v. Cameron* 1966, 456). In *Nason v. Superintendent of Bridgewater State Hospital* (1968), the Supreme Judicial Court of Massachusetts found a constitutional right to treatment for a patient found incompetent to stand trial and whose further court proceedings required his return to competence. This court grounded

its decision in the Due Process Clause of the Fourteenth Amendment.

The right to treatment was first applied to civilly committed patients in *Wyatt v. Stickney* (1971), initially a U.S. District Court case (eventually affirmed by the Eleventh Circuit Court of Appeals), which challenged the deplorable conditions in the Alabama state hospitals. In a series of far-reaching decisions, Judge Johnson adopted the theory articulated in *Rouse v. Cameron*. In the third *Wyatt* decision, Judge Johnson indicated that Alabama had failed to provide "(1) a humane psychological and physical environment; (2) qualified staff in numbers sufficient to administer adequate treatment; and (3) individualized treatment plans" (*Wyatt v. Stickney* 1972, 375). The court delineated "Minimum Constitutional Standards for Adequate Treatment of the Mentally Ill" for each of these three areas, outlining in great detail the minimal standards that the state would be required to meet. The staffing standards are of particular interest.

Other courts adopted Judge Bazelon's analysis and findings, applying them to institutions for the "mentally retarded." In *New York State Association for Retarded Children v. Rockefeller* (1973), the so-called "Willowbrook case," the court found that institutionalized mentally retarded persons had a right to protection from harm but no clear right to treatment. To this point, no case had been heard by the U.S. Supreme Court.

U.S. Supreme Court: 1975–1982

During this time period, the U.S. Supreme Court had three major opportunities to determine that a "right to treatment" existed, but declined to do so. In *O'Connor v. Donaldson* (1975), Justice Stewart, writing for the majority of the Supreme Court, indicated that

> There is no reason now to decide whether mentally ill persons dangerous to themselves or to others have a right to treatment…this case raises a single, relatively simple but nonetheless important question concerning every man's constitutional right to liberty. (*O'Connor v. Donaldson* 1975, 573)

Rather, the Court found:

> A state cannot constitutionally confine without more a non-dangerous individual who is capable of surviving safely in freedom by himself or with the help of willing and responsible family members or friends. (Ibid., 576)

To emphasize the absence of a finding of a right to treatment, in a concurring opinion Chief Justice Burger held:

> no other basis for equating an involuntarily committed mental patient's unquestioned constitutional right not to be confined without due process of law with a constitutional right to treatment. (*O'Connor v. Donaldson* 1975, 587–588, emphasis in original)

However, although Chief Justice Burger's opinion appears to reject the concept of a right to treatment, the majority opinion, while failing to find such a right, does not explicitly reject it either. In fact, the use of the phrase "without more" has been interpreted by some to mean that nondangerous individuals cannot be hospitalized involuntarily *without treatment*. Hence, lower courts could, and have, considered the right in subsequent litigation.

Having failed explicitly to find a right to treatment for the mentally ill, the Supreme Court turned its attention to the mentally retarded. In *Halderman v. Pennhurst State School and Hospital* (1977), the U.S. District Court held:

> that when a state involuntarily commits retarded persons, it must provide them a reasonable opportunity to acquire and maintain those life skills necessary to cope as effectively as their capacities permit.

The Supreme Court again did not find a constitutional basis for a right to treatment or habilitation, but rather determined in this case that the Developmental Disabilities Assistance and Bill of Rights Act (an act establishing a federal–state grant program) did not guarantee to institutionalized mentally retarded persons any such rights (*Pennhurst State School and Hospital v. Halderman* 1981).

In *Youngberg v. Romeo* (1982), the Supreme Court did finally address the substantive due process rights of mentally retarded persons involuntarily committed to institutions. The Court specifically addressed whether such persons had rights under the Fourteenth Amendment to "(i) safe conditions of confinement; (ii) freedom from bodily restraint; and (iii) training or 'habilitation'" (*Youngberg v. Romeo* 1982, 309). The Court opined:

> Respondent has constitutionally protected liberty interests under the Due Process Clause of the Fourteenth Amendment to reasonably safe conditions of confinement, freedom from unreasonable bodily restraints, and such minimally adequate training as reasonably may be required by their interests…. And in determining what is "reasonable," courts must show deference to the judgment exercised by a qualified professional, whose decision is presumptively valid. (*Youngberg v. Romeo* 1982, 307)

The "training" aspect of this case appeared to particularly interest members of the Court. Justice Blackmun, in a concurring opinion, articulated that the level of training

should be "that habilitation or training necessary to *preserve* those basic self-care skills he possessed when he first entered Pennhurst" (*Youngberg v. Romeo* 1982, 327, emphasis in original). On the other hand, in his concurring opinion, Chief Justice Burger wrote:

> I would hold flatly that respondent has no constitutional right to training, or "habitation," per se.... I agree with the court that some amount of self-care instruction may be necessary to avoid unreasonable infringement of a mentally retarded person's interests in safety and freedom from restraint, but it seems clear to me that the Constitution does not otherwise place an affirmative duty on the state to provide any particular kind of training or habilitation – even such as might be encompassed under the essentially standardless rubric "minimally adequate training" to which the Court refers. (Ibid., 329–330)

Immediately post-*Youngberg*: 1983–1990

The Supreme Court did much less than those who championed the right-to-treatment cause would have hoped. Even before the Supreme Court issued decisions regarding these cases, psychiatrists with particular expertise in these matters were doubtful of the usefulness of the judicial process for ensuring this right. Stone (1975) argued, "The right to treatment cannot come from complicated judicial discourse about civil rights and about civil liberties." Roth (1977) lamented, "I do not believe that the so-called right-to-treatment laws will ever provide the help that physicians hoped they would in ensuring that patients receive needed and effective treatment."

The "right to treatment" continued to struggle throughout this period. Litigation in federal court attempting to broaden *Youngberg* is best exemplified by the long struggle between Morton Birnbaum and the state of New York, which began as *Woe v. Matthews* (1976) and ended as *Foe v. Cuomo* (1989). The major advances in the right to treatment in the 1980s occurred pursuant to the Civil Rights of Institutionalized Persons Act (CRIPA) of 1980. This act authorizes the U.S. government to institute a civil action against any state whose officials, employees, or those acting on their behalf are "subjecting persons residing in or confined to an institution to egregious or flagrant conditions which deprive such persons of any rights, privileges, or immunities secured or protected by the Constitution or laws of the United States causing such persons to suffer grievous harm" (Civil Rights of Institutionalized Persons Act, 42 U.S.C. Sec. 1997 et seq.). Under this authority, the Civil Rights Division of the U.S. Justice Department has been able to bring the right to treatment substantially closer to a reality for thousands of individuals in state psychiatric hospitals and in developmental disabilities/mental retardation facilities. It has done so by applying the standards of *Youngberg*, and has accomplished its end largely through the vehicle of consent decrees. One can ascertain the progress that made by comparing the staffing parameters of the *Wyatt* case, the first consent decree in 1984 (*United States v. Indiana* 1984), with a consent decree initiated in the late 1980s (*United States v. Hawaii* 1991).

ADA and *Wyatt*: 1990–2003

The Americans with Disabilities Act (ADA), passed on July 26, 1990, establishes "a clear and comprehensive prohibition of discrimination on the basis of disability." The Act has four major components: Title I applies to employment; Title II to public services; Title III to accommodations required of private entities; and Title IV to telecommunication services. Enforcement entities vary by Title. Title I is enforced by the Equal Employment Opportunity Commission (EEOC); Titles II–IV are enforced by specific government agencies, such as Department of Housing and Urban Development's enforcing of public housing; and the U.S. Department of Justice's (USDOJ's) enforcing all areas of Titles II–IV not enforced by any other federal agency (Wylonis 1999). Title II is of greatest interest in the area of "right to treatment," in that this title covers state and local government services and therefore includes state and county psychiatric hospitals (ADA 1990).

The part of Title II most pertinent to the right to treatment is contained in Section 12132, which indicates, "no qualified individual with a disability shall, by reason of such disability, be excluded from participation in or be denied the benefits of the services, programs, or activities of a public entity, or be subject to discrimination by any such entity." The "integration regulation," one of many regulations that were required to be promulgated to operationalize this Act, states, "A public entity shall administer services, programs, and activities in the most integrated setting appropriate to the needs of qualified individuals with disabilities" (28 C.F.R. 35.130(d)). The "reasonable-modifications" regulation states that public entities must make "reasonable modifications" in order not to discriminate "'on the basis of disability." However, these public entities are not required to "fundamentally alter" the nature of their programs (28 C.F.R. 35.130(b)(7)).

Although the ADA addresses public institutions, it generally was not viewed as a way to improve services within state and county psychiatric hospitals, but rather as a way to force states to transition patients out of these institutions. The ADA has been a vehicle that has helped to further the now five-decade-old movement of patients from institutional to noninstitutional settings, which are collectively generally referred to as "in the community" (Geller 2000a).

With regard to the *Wyatt* case, on January 20, 2000, all parties reached a settlement agreement; a fairness hearing

was held on May 4, 2000, and a decision was reached on July 13, 2000. The settlement agreement endorsed by the court included the following components:

1. Accreditation: All mental illness facilities must maintain Joint Commission on Accreditation of Health-Care Organizations (JCAHO) accreditation.
2. Advocacy programs: All mental illness facilities must maintain an advocacy staff to educate patients about rights, investigate complaints of rights violations, and monitor conditions of facilities and certified community programs.
3. Census reduction: Specific target census reductions were set, but no facility closures were required.
4. Community placement: Facilities were required to develop and implement a plan for "out-placements" and concurrently increase community-based placements and services.
5. Public education: States were required to institute a comprehensive, state-wide plan to enhance the public's appreciation for the abilities, needs, and rights of persons with mental illness.
6. Quality improvement: Facilities must maintain adherence to current policy and procedures and continue Continuous Quality Improvement Systems.
7. Safety and protection: Facilities must respond in a timely manner to allegations of abuse and neglect with trained employees using standard procedures.
8. Treatment and habilitation: Alabama Disabilities Advocacy Program can have input into individualized treatment plans, and consultants will be hired to address special needs populations (e.g., the dually diagnosed mental illness/mental retardation, organic/brain injured, physically handicapped, HIV/AIDS, self-injurious, others) and to review and make recommendations concerning the use of seclusion and restraint (*Wyatt v. Sawyer* 2000).

Although the 2000 settlement agreement in the *Wyatt* case specifically addresses conditions in the state facilities of Alabama, it also addresses institutional downsizing, expansion of community services, and the monitoring of some of these community services. This settlement agreement was scheduled to end when all parties agreed that Alabama had completed "certain obligation undertaken in the agreement" (*Wyatt v. Sawyer* 2000). On December 5, 2003, Judge Myron Thompson held a fairness hearing. In this hearing, he determined that the state had complied with the 2000 settlement agreement. As a result, the *Wyatt* case was terminated after over 30 years of ongoing litigation. Mental health professionals and their professional organizations will continue to monitor with great interest if and how treatment for those with serious mental illness is actually advanced through this and other litigation.

As a footnote to this era, it is worth noting that CRIPA is still active law in the United States, although new wrinkles have appeared. States are continuing to enter into settlement agreements with "Plans for Continuous Improvement." Newer agreements generally proffer somewhat different requirements than earlier consent decrees. In 1999, Hawaii changed course in its efforts to improve Hawaii State Hospital, announcing its intent to alter the nature of the hospital by modifying it into a "secure rehabilitation facility" (Act 119, 1999 State of Hawaii Legislature). In 2000, amid litigation, Florida announced (*Johnson v. Murphy* 1987) that it would close the state hospital that was the subject of a suit (Krueger 2000) and did, in fact, close that hospital in 2002.

The end of *Wyatt* to the present

The *Wyatt* case, which ended in 2003 after over 30 years of litigation, serves as an example of judicial oversight and continued monitoring as a means to verify states' compliance in improving the conditions in their facilities. With regard to institutional treatment since *Wyatt*, although the ADA helped promote "community treatment," reformers' focus currently remains on conditions within these institutions. According to Fisher et al. (2009), a major focus of mental health policy over the past 50 years has been closing state psychiatric hospitals. There has been a 95% reduction in the country's state hospital population. Despite this, over 200 state hospitals remain operational in the United States (Fisher et al. 2009). One study found that 50 long-term state hospital beds per 100,000 population are needed (Torrey et al. 2008). However, in 2010 only 14.1 beds per 100,000 population were available (Torrey et al. 2012). Lamb and Weinberger (2013) reported that a significant number of individuals who may otherwise meet criteria for acute psychiatric hospitalization are, instead, incarcerated, possibly because of the dearth of state hospital beds. "Deinstitutionalization" legislation has helped facilitate the release of many individuals from state hospitals but has also demonstrated that community mental health systems are not perfectly equipped to help ensure a smooth transition from institution to community for these individuals. (Deinstitutionalization legislation obviously increased the number of individuals in the community who required ongoing mental health treatment.) In fact, many observers have noted that state hospitals may be necessary entities to provide care to specific subsets of the "seriously mentally ill" population (e.g., forensic committees). As a result, 2003–2013 may represent the first decade since the start of deinstitutionalization during which there has not been a continuous flow of patients out of state hospitals.

The ADA was amended in 2008 with the passage of the ADA Amendments Act (ADAAA), which became effective on January 1, 2009. The ADAAA was a response to multiple decisions by the U.S. Supreme Court that had interpreted the ADA's original text. The ADAAA explicitly overrode those decisions and rejected portions of the regulations published by the EEOC. Although this Act kept the same definition of disability as the original ADA (i.e., "physical or mental impairment that substantially limits

one or more major life activities of such individual…"), it changed the manner in which certain statutory terms, such as "'substantially limits," should be interpreted. It also expanded the definition of "'major life activities." In effect, it both broadened and clarified the definition of "disability," with likely implications on the number of individuals covered by the ADA (ADAAA Summary and Resources 2009). An increase in the number of individuals covered by the ADA may lead to an increased funding requirement to continue current programs' compliance with the ADA.

CRIPA remains active 30 years after its introduction. However, its future impact on state institutions is unclear. It has been reported (Geller and Lee 2013) that the "findings letters" generated by the DOJ in psychiatric hospital CRIPA cases, which usually contain recommended remedial measures for state institutions, "were often cut and pasted from one Findings Letter to another, with limited variation in the recommendation." As of January 2009, the last month that President George W. Bush was in office, the Department of Justice had a total of six settlement agreements in various states across the country, including Hawaii, Washington, South Carolina, Connecticut, California, and Tennessee (Shapiro 2009). Last-minute settlement agreements do not necessarily reflect meaningful progress, but do offer the opportunity to foster change. As of the end of fiscal year 2011–2012, the special litigation section of the Civil Rights Division of the DOJ, which enforces CRIPA, "had active CRIPA matters and cases involving 163 facilities in 32 states, the District of Columbia, the Commonwealths of Puerto Rico and the Northern Mariana Islands, and the Territories of Guam and the Virgin Islands" (DOJ 2011).

When discussing institutional treatment, it is important to remember that it does not just occur in the United States, but also in multiple other nations. Over the past decade, the World Health Organization (WHO) has published educational materials on mental health and human rights violations. The WHO has discussed the absence of community mental health treatment services and its impact on the ongoing institutionalization of those with mental illness. In 2008, the United Nations Convention on the Rights of Persons with Disabilities (CRPD) was developed and was considered a "major step forward in promoting and protecting the rights of people with mental disabilities" (WHO 2007).

COMMUNITY TREATMENT

The right to treatment in the community initially was based on the right to treatment in the "least restrictive alternative" (LRA), a doctrine first articulated in mental health cases by Judge David Bazelon in *Lake v. Cameron* (1966). That landmark case prohibited commitment if less "restrictive" treatment alternatives were possible. Although LRA is a convoluted concept at best (Hoffman and Foust 1977; Gutheil et al. 1983; Munetz and Geller 1993; Fisher et al. 1995), it has provided the basis for extending the right to treatment through both state statutes and the federal courts.

Most states have statutes conferring a right to appropriate treatment and services, and many states have statutes that explicitly address a right to treatment in the LRA (Beis 1984; Brakel et al. 1985). In *Dixon v. Weinberger* (1975), a case involving the patients of Saint Elizabeth's Hospital in the District of Columbia, the court, in basing its decision on statutory grounds (the District of Columbia Hospitalization of the Mentally Ill Act), found that patients were guaranteed a right to treatment and that this right was no less than a right to treatment in the LRA. Unfortunately, throughout most of its existence, the *Dixon* case has resulted in considerably more process than outcome (Armstrong 1979; *Dixon v. Sullivan* 1989; Advocates welcome agreement… 2000). Through a consent order in late winter of 2000, however, it was hoped that returning the mental health system to the District (by ending the receivership) would hasten compliance with the 25-year-old court decision (*Dixon v. Miller* 2000; Miller 2000).

In Arizona, the Superior Court of Arizona ruled in *Arnold v. Sarn* (1985, 40) that pursuant to state statute, the Arizona Department of Health Services, the Arizona State Hospital, and the Maricopa County Board of Supervisors were obligated to provide "a continuum of care" through a "unified and cohesive system of community mental health care that is well integrated." This "continuum" was defined by the court as including case management, residential services, day treatment, outreach, medications, outpatient counseling, crisis stabilization, mobile crisis services, socialization, recreation, work adjustment, and transportation. Santiago (Santiago et al. 1986; Santiago 1987) cogently summarized this process in Arizona through the mid-1980s.

The plaintiff class and the state of Arizona and Maricopa County entered into a supplemental agreement in December 1998. As a result of this agreement, the defendants are required to complete a "needs assessment" on a sample of class members; determine the services necessary to meet these needs and the methodology to create these services; develop interim and long-term plans for the operation of clinical teams; and create standards and conduct performance reviews (*Arnold v. ADHS* 1998). By August 1999, a study of the mental health services needs of class members had been completed by the Human Services Research Institute of Cambridge, Massachusetts (Personal communication, H. Stephen Leff to Ronald Smith, August 6, 1999). The 2000 Independent Audit Report of the Office of the Monitor found that "only modest substantive progress has been made in the areas of assessment, service planning, service provision, or adequate monitoring by the clinical teams" (*Arnold v. Sarn* 2000, I) and refers to these results as "disheartening." In 2004, an audit released by the Office of the Monitor revealed that Arizona was out-of-compliance with requirements set forth in *Arnold v. Sarn* (Senate Research 2009). Fast forward to 2010; because of the state's budget crisis, the Superior Court of

the State of Arizona issued an order regarding joint stipulation to stay litigation in the case during the fiscal budget crisis (O'Connor 2010). This resulted in a freeze in funding for the Office of the Monitor, which had been the only mechanism by which to evaluate the state's compliance. Following the end of the stay, an agreement was entered into May 2012. As of 2013, the 30-year-old *Arnold v. ADHS* (Sarn) case remains open.

One of the most far-reaching cases to date, in terms of its outcome, has been *Brewster v. Dukakis* (1976). Plaintiffs brought an action against the Commonwealth of Massachusetts claiming violations of state statutes and federal entitlements and asserting their right to be treated in the LRA. Two years later, a consent decree was signed (*Brewster v. Dukakis* 1978) that mandated a "comprehensive community mental health and retardation system to include no less than residential environments; non-residential treatment, training, and support programs; and management services to coordinate and monitor the network of environments and programs." The consent decree focused on those persons of western Massachusetts who had been, were, or could be patients at the Northampton State Hospital. Although the overall outcomes have been mixed (Geller et al. 1990a,b; Geller 1991a), some achievements have been remarkable. A decade after the consent decree was signed, every patient in the hospital on the day of the signing had been discharged at least once (Geller et al. 1990). In the area covered by the consent decree, the Commonwealth of Massachusetts managed to establish the best-funded community residential system in the United States (Geller and Fisher 1991). And 10 years after the decree took effect, the attorney who brought the suit concluded, "By most accounts, few persons are still institutionalized in western Massachusetts or are at risk of hospitalization as a result of a lack of an appropriate, less restrictive alternative" (Schwartz and Costanzo 1987, 1400).

Currently, the major changes in community-based treatment are being fuelled by courts' applications of the ADA to persons in psychiatric institutions. Prior to the first case heard by the U.S. Supreme Court, there were a series of cases in lower federal courts that essentially found that persons with mental illnesses must receive care and treatment in community settings where professional judgment finds such treatment to be appropriate (Petrila 1999). An interesting example of such cases is *Kathleen S. v. Department of Public Welfare* (1998, 1999), a Pennsylvania case that focused on the closing of Haverford State Hospital. The thrust of the case was: Which, if any, patients could be transferred to Norristown State Hospital (another Pennsylvania state hospital)? The court divided the patients into three subclasses and found the following:

- Those identified by the state as appropriate for community placement now—placement immediately.
- Those identified by the state as "placeable" during the next three years—place all within 1.5 years.
- Those identified by the state as not "placeable" and requiring hospital level of care—transfer to Norristown State Hospital, but conduct independent evaluations by a psychologist or psychiatrist within 6 months to determine appropriateness for community treatment.

The state appealed the decision. The ultimate outcome was a settlement agreement between the two parties that made no changes for the first subclass, extended the date for the second subclass by 3 months, and indicated that all members of the third subclass identified as appropriate for community services would receive them no later than 6 months after the "determination of appropriateness" deadline. This case not only supported the right to community-based care and treatment, but established quite ambitious time frames for the state to accomplish this objective.

The case of *Olmstead v. L.C.* (1999) is the hallmark U.S. Supreme Court decision to date on the application of the ADA to persons in state hospitals. The case involved two women with mental retardation—one of whom also had schizophrenia and the other of whom was diagnosed with a personality disorder—who were being kept in a Georgia state hospital despite the fact that treatment professionals had concluded each could be appropriately treated in community-based programs. The Supreme Court, in a 6–3 decision, found that for any person with a mental disability, community-based treatment rather than institutional placement is required of the states when: "(1) the state's treatment professionals have determined that community placement is appropriate; (2) the transfer from institutional care to a less restrictive setting is not opposed by the affected individual; and (3) the community placement can be reasonably accommodated, taking into account the resources available to the state and the needs of others with mental disabilities" (*Olmstead v. L.C.* 1999, 607). The majority found that the "unjustified isolation…[of persons with mental disabilities] is properly regarded as discrimination based on disability" (*Olmstead v. L.C.* 1999, 597). This finding is rooted in the majority's opinion that "institutional placement of persons who can handle and benefit from community settings perpetuates unwarranted assumptions that persons so isolated are incapable or unworthy of participating in community life" (*Olmstead v. L.C.* 1999, 600) and that institutional confinement "severely diminishes the everyday life activities of individuals, including family relations, social contacts, work options, economic independence, educational advancement, and cultural enrichment" (*Olmstead v. L.C.* 1999, 601).

In the past, commentators have noted that the decision is "vague," "weak," and "fractured" (Herbert and Young 1999). Others have remarked that "the decision is unlikely to precipitate the widespread creation of community-based services for persons with mental disabilities" (Appelbaum 1999). After the *Olmstead v. L.C* case, there were a number of lawsuits challenging institutionalization of individuals with psychiatric, physical, and/or developmental disabilities. The DOJ has participated in, filed, or

joined "*Olmstead* suits" in 21 states (Bagenstos 2012). In 2009, the Department of Justice's Civil Rights Division decided to enhance enforcement of the Supreme Court's decision in *Olmstead v. L.C.* President Barack Obama introduced "The Year of Community Living" and directed the Administration to increase enforcement efforts (Office of the Press Secretary, The White House, 2009). In 2010, the Department of Justice settled a long-running dispute with the state of Georgia in the *Olmstead* case. The state agreed to spend $77 million over the next 2 years to set up community-based care for up to several thousand people with mental illness and disabilities who then lived in state institutions (Shapiro 2010). Funding has been just one of the obstacles preventing the *Olmstead* decision from fully realizing its presumptive intended effects regarding community treatment. In 2012, Assistant Attorney General Thomas E. Perez stated, "More than a decade after *Olmstead*, many individuals across the country who can live in the community and want to live in the community remain unnecessarily institutionalized."

The Affordable Care Act (ACA) also may improve funding and access to community treatment. The ACA reportedly will allow an additional 32 million individuals to obtain mental health or substance use disorder (MH/SUD) benefits. Beginning in 2014, the ACA requires all new small group and individual private market plans to cover MH/SUD services as part of the health-care law's "Essential Health Benefits" category, and insurers are required to cover mental health benefits at the same level as medical and surgical benefits. This builds on parity requirements set forth in the 2008 Mental Health Parity and Addiction Equity Act (MHPAEA). The MHPAEA specifies that "the financial requirements and treatment limitations imposed on mental health and substance use disorder benefits cannot be more restrictive than the predominant financial requirements and treatment limitations that apply to substantially all medical and surgical benefits" (U.S. Department of Labor 2013). In addition, under the ACA, insurers will no longer be allowed to deny individuals coverage because of pre-existing mental health conditions. The ADA, MHPAEA, and ACA are legislative vehicles designed to benefit a number of individuals, including those with physical or mental disabilities. It is not yet clear if the goals of these pieces of legislation will be realized.

SUMMARY

Where is the "right to treatment" at this point? Perhaps its status can best be described as "evolving." To whatever degree services in community settings are improved, the number of individuals who are in institutions, but would be appropriate for care and treatment outside of institutions, continues to expand. A court decision stirred the winds of change by finding that an individual can make claims simultaneously under the ADA and under law governing Social Security Disability Insurance (Broadman 2000). Meanwhile, Alberta Lessard, the plaintiff named in *Lessard v. Schmidt* (1972)—a case that addresses the bases for and procedures of civil commitment—has failed several times over the years to obtain care and treatment from the public psychiatric system in Milwaukee. This is because, in a system of downsized acute inpatient treatment, "they said I wasn't sick enough," said Ms. Lessard (Mental-illness ruling hinders patients 2000).

Although there is significant activity around the right to treatment, a universal definition of the term is not agreed on. The concept "least restrictive alternative" was never adequately defined (Munetz and Geller 1993); the concept "most integrated setting" uses new language but is equally inadequately defined. If an individual has a right to "community-based services," do we not need to define "'services" and "community" (Geller 1991b, 2000b)? Until such definitions are clear, and until such services are uniformly a reality, the right to treatment remains what, in current parlance, could be referred to as an "unfunded mandate"; this "right" remains simply an unfulfilled promise for persons who would be the beneficiaries of it. When the entities that govern the judicial and funding processes are simultaneously the enforcers of said policies, there are bound to be barriers to progress. Challenges remain related to altering state mental health systems in an effort to improve/increase the right to treatment through judicial means (without addressing funding); developing viable implementation strategies; and defining scope of coverage (Feng 2012). These challenges ensure that this will continue to be an arduous process.

SUMMARY KEY POINTS

- The right to treatment has been variously based on the Eighth Amendment (proscription against cruel and unusual punishment), the Fourteenth Amendment (both the Due Process and the Equal Protection Clauses), the "quid pro quo" rationale (i.e., treatment is due to civilly committed patients in exchange for enforced confinement), and the "least restrictive alternative" doctrine ("deprivations of liberty solely because of dangers to ill persons themselves should not go beyond what is necessary for their protection") (*Lake v. Cameron* 1966, 660).
- A large portion of right-to-treatment litigation has focused on establishing standards of care and

concomitant staffing patterns in treatment facilities. In addition, legislative and judicial actions have contributed to the deinstitutionalization of patients and led to the adoption of "least restrictive alternatives" for patients.
- The U.S. Supreme Court has yet to provide a definitive ruling that guarantees and clarifies the "right to treatment," "least restrictive alternative," or "community-based services."

Treatment refusal in psychiatric practice

DEBRA A. PINALS, ARIANA NESBIT, AND STEVEN K. HOGE

INTRODUCTION

Historically, individuals with mental illness have had more limited rights to refuse treatment than those without mental illness. This was primarily the case for patients committed to psychiatric facilities, but also applied to some voluntary patients (Appelbaum 1994). Until the last quarter of the twentieth century, society granted psychiatrists the authority to determine the course of treatment for committed patients and, if necessary, to administer the treatment over the patient's objection. Now, virtually every jurisdiction recognizes that all patients, regardless of their commitment status, have some rights with regard to treatment refusal. In order to understand the current legal approaches to treatment refusal, it is necessary to explore the factors that led to this dramatic change in the nature of doctor–patient relationships in psychiatric institutions. Developments in mental health case law, the evolution of the informed consent doctrine, and public perception about the quality of care delivered in psychiatric institutions all played important roles with respect to the currently recognized right to refuse treatment (Hoge et al. 1989; Perlin 1993; Appelbaum 1994; Winick 1997; Appelbaum and Gutheil 2007).

A crucial development was the shift in the legal justification for civil commitment away from paternalistic grounds—operationalized in a "need-for-treatment" criterion—to grounds rooted primarily in the police powers of the state and dangerousness-oriented criteria. When the legal standard for involuntary hospitalization was based on need for treatment, a post-commitment right to refuse treatment made no conceptual sense. However, when states adopted the new dangerousness-oriented criteria, it became possible for courts to separate the need for confinement from the need for treatment and to question why treatment was essential once the threat of harm had been minimized (Hoge et al. 1989; Appelbaum 1988, 1994; Appelbaum and Gutheil 2007). Dangerousness is generally defined as danger to others or danger to self either by suicide or by an inability to care for oneself, the so-called "grave disability" standard (Large et al. 2008). The consequences of requiring dangerousness for commitment have been discussed from numerous vantage points. For example, when dangerousness is necessary for commitment, only those who have crossed a certain risk threshold can be admitted involuntarily, while those who are less ill but deteriorating symptomatically or functionally because of medication refusal are not eligible for intensive treatment aimed at preventing risk-related behavior. Thus, when an individual is admitted involuntarily to a hospital, treatment considerations require a rapid, planned approach, especially in those cases where the patient objects to treatment.

Another major development occurred in the 1960s, when clinical and legal pressures challenged the notion that involuntarily committed patients were globally incompetent to make decisions. As patients moved out of state hospitals, committed patients were unable to successfully reintegrate into the community at least partially because of the presumption that they were incompetent to sign leases or enter into other contractual arrangements. A mental health patients' rights advocacy movement grew and won for patients greater legal equality with non-mental-health patients, who had always retained the legal presumption of competence. As a result, by the early 1970s, the presumption that committed patients were globally incompetent had virtually disappeared (Appelbaum 1994).

The presumption of competence for committed patients was a crucial development that became even more significant with the maturation of the doctrine of informed consent. From a clinical and scientific perspective, an enormous amount of research effort has been put forth in the past decade to elucidate capacities for persons with mental illness related to decision making in both treatment and research settings. This literature has further supported the notion that persons with mental illness are not, by definition, incompetent to make their own decisions. Careful examination of the patient's treatment-specific decision-making capacity is required before an individual can be deemed incompetent (Appelbaum and Gutheil 2007).

Doctors also are required by informed consent laws, case law, and ethics to describe to the patient more than just the

nature of the proposed treatment. In order to obtain a valid informed consent, doctors must also disclose the risks and benefits of the treatment, alternatives to the proposed treatment, the risks and benefits of the alternative treatment, and the risk of no treatment. This expanded scope of disclosure enables individualized decision making, with the emphasis on patient autonomy to choose among various options. Thus, the doctrine of informed consent made explicit that treatment choice is inherently an individual value judgment and not an objective determination made by a physician or other authority on scientific or medical grounds. In other words, medical decision-making authority shifted dramatically from physicians to patients with the evolving informed consent doctrine. The doctrine also provided courts with a convenient analytic tool, the risk–benefit ratio, by which laypeople, judges, or other surrogate decision makers could evaluate proposed and alternative treatments (Hoge et al. 1989; Appelbaum 1994; Appelbaum and Gutheil 2007). For further discussion of informed consent, see Chapter 14.

Finally, concerns about the quality of care in psychiatric institutions also reinforced the notion that patients have a right to refuse treatment. Society had long given psychiatrists broad discretion to make treatment decisions in psychiatric institutions. This discretion was based on the presumption that treatment decisions would be in the best interests of patients and that patients would receive individualized treatment based on their specific needs. This long-standing granting of authority also applied to the use of antipsychotic medications. Because antipsychotic medications were the first effective treatment for individuals with severe mental illness, and because they were initially regarded as miracle drugs, at first, there were no reasons to question their use. However, over time, our understanding of the effects of these medications changed, and people no longer assumed that psychiatrists were always prescribing beneficently (Erickson et al. 2007; Brakel and Davis 2008). Specifically, the inherent limitations of antipsychotic medications were recognized, and it was realized that the medications were not a panacea for all mental illness. In addition, the risks of treatment were increasingly appreciated as long-term administration led to potentially irreversible tardive dyskinesia in a significant minority of patients (Slovenko 2000).

Especially in the early years of use, a common concern was that these medications were being used to sedate patients for the convenience of the staff. Even worse, some claimed that patients received these medications as punishment, and some institutions were alleged to have insufficient resources to safely and adequately monitor their patients' pharmacotherapy (Hoge et al. 1989) and that the "dangers" of antipsychotic medication were minimized (Whitaker 2002). More recently, concerns about metabolic syndrome and other serious side effects have been raised (Young et al. 2015). As these risks have been recognized, and as the concepts of patient autonomy and self-determination have made gains in psychiatric care, the right to refuse treatment has persisted, and it has become even more important to provide patients with the data necessary to make informed treatment decisions (Parsons and Kennedy 2007).

LEGAL CRITERIA

In view of the diverse factors underlying the recognition of a right to refuse treatment, it is not surprising that a variety of legal approaches have emerged that differ in defining the contours of the right and in the prescription of procedural protections (Appelbaum 1994; Pinals and Mossman 2012). Rules governing treatment refusal vary across jurisdictions. For example, definitions of what constitutes incompetence, or an emergency sufficient to override treatment refusal vary greatly. Thus, it is necessary that psychiatrists familiarize themselves with the relevant case law, statutes, and regulations related to their specific practice setting.

Legal approaches to the adjudication of treatment refusal can be categorized into two broad groups, based on whether they are driven primarily by concerns about patient rights or by concerns about the quality of patient care (Appelbaum 1994). These fundamentally different legal approaches are typified by the two initial cases in this area. In *Rogers v. Commissioner of Mental Health* (1983), the Massachusetts Supreme Judicial Court adopted a "rights-driven" model, relying on state statutes and common law principles; in contrast, in *Rennie v. Klein* (1983) the Third Circuit of the U.S. Court of Appeals found that a "treatment-driven" model satisfied U.S. constitutional requirements.

As case law in each of these areas evolved, several constitutional arguments have been made justifying a right to refuse treatment. Among these constitutional arguments are the right to free speech, based in part on the First Amendment; the right to be free of cruel and unusual punishment, based on the Eighth Amendment; the right to due process, based upon the Fourteenth Amendment; and the right to privacy, derived in a general sense from the penumbra of the First, Fourth, Fifth, and Ninth Amendments (Ciccone et al. 1990; Hermann 1990).

Rights-driven models

Rights-driven models are primarily concerned with individuals' autonomy and thus seek to protect patients' rights to determine the course of their treatment. These rights-driven models have at their core an informed consent analysis: competent patients have the right to refuse treatment, absent an emergency; only the treatment refusals of incompetent patients may be overridden. Most jurisdictions with a rights-driven model will require a formal, legal adjudication of incompetence, but some variants of this model place the determination of competence in the hands of psychiatrists or a multidisciplinary board (Appelbaum 1994; Appelbaum and Gutheil 2007).

In general, those states that hold formal judicial hearings do not place the treatment decision in the hands of clinicians, even following a determination of incompetence. Courts, such as the *Rogers* court, have feared that

psychiatrists will be unable to curb past abuses because competing interests—maintaining order in the facility, discharging patients, pleasing family members—may influence their treatment decisions. Instead, in many jurisdictions, the decision-making authority for the patient is vested in a guardian. In other jurisdictions (e.g., Massachusetts and New York), the court may make the treatment decision itself. Standards for decision making may involve a variety of models (Wettstein 1999; Appelbaum and Gutheil 2007). In one of the more common prototypes, treatment decisions are made based on what is considered by an objective decision maker (e.g., the court or a guardian) to be in the best interests of the patient.

An alternative, more rigorous standard of decision making in rights-driven jurisdictions is the "substituted judgment" model. In this model, the courts attempt to approximate decisions regarding treatment based on what the patient would have wanted if competent. For example, in the *Rogers* case, the courts concluded that a substituted judgment determination requires that evidence including the following should be considered: the patient's stated preferences, experienced side effects of the medication, family preferences, prognosis with and without treatment, and any religious considerations that may have influenced the patient's treatment decisions if competent (*Rogers v. Commissioner of Mental Health* 1983). This method, although respectful of a patient's autonomy, can be difficult to implement if the patient was never competent (*Superintendent of Belchertown State School v. Saikewicz* 1977) or if there is no family or available means to ascertain the patient's preference during times when they may have been competent.

Treatment-driven models

Treatment-driven models, which view patients' right to refuse treatment as being limited to inappropriate care, have been devised by courts and legislatures. The notion that civil commitment is intended to bring about treatment—and not merely confinement—is what catalyzes the treatment-driven model of adjudicating refusal. Committed patients are entitled to refuse treatment only when it is not truly prescribed for therapeutic ends. Because the standard for overriding refusal is based on the appropriateness of the prescribed treatment, treatment-driven models place the primary authority to override refusal in the hands of professionals—such as treating psychiatrists, medical directors, independent psychiatrists, or multidisciplinary boards—who can identify misuses of medication. Moreover, because the determinations are made by clinicians, the procedures for review are often informal and do not require judicial hearings (Appelbaum 1994).

The preference for one model over the other generally depends on one's role with the treatment-refusing person. Psychiatrists generally favor treatment-driven models of adjudicating treatment refusal because they recognize the primacy of clinical decision making and therapeutic goals, and such a model reduces the risk that patients who need medications will go untreated. Administrators also favor such models because they minimize the diversion of clinical time from treatment efforts. Legal and patients' rights advocates generally object to treatment-driven models. In these models, they perceive lesser protections for the rights of committed patients, which they assert can result in disadvantage, loss of autonomy, and diminished dignity for persons with mental illness (Table 18.1).

Table 18.1 Legal approaches to the adjudication of treatment refusal

Legal approach	Prototypical legal case	Key differences
Rights-driven	*Rogers v. Commissioner of Mental Health* (1983)	Deference to judicial decision Requires affidavit and court decision
Treatment-driven	*Rennie v. Klein* (1983)	Deference to medical decision maker Often requires layered clinical reviews and permissions

Differences between state and federal courts

State and federal courts have charted different courses in deciding right-to-refuse-treatment cases, as was signaled by the *Rennie* and *Rogers* decisions. Federal courts typically have been willing to show deference to psychiatrists' judgments regarding committed patients. The U.S. Supreme Court, for example, specifically instructed the Third Circuit Court of Appeals to take the Supreme Court decision of *Youngberg v. Romeo* (1982) into consideration in deciding *Rennie v. Klein*. In *Youngberg*, a case involving a civilly committed, intellectually disabled person's right to treatment and freedom from restraint, the Supreme Court found that the exercise of professional judgment was sufficient protection of patients' rights when their liberties conflicted with therapeutic purposes.

The U.S. Supreme Court also decided a case involving the right of a prisoner with mental illness to refuse treatment, *Washington v. Harper* (1990). The Court upheld the state of Washington's regulatory scheme, a variant of the treatment-driven model that predicated override of treatment refusal on a finding that the patient met the "dangerousness standard" for commitment and needed treatment. The regulations established procedures for review, including the right to notice, a hearing before a professional panel, and lay representation. Although the decision could be read narrowly as affecting only prisoners, since then, in *United States v. Loughner* (2012), the Ninth Circuit Court of Appeals determined that *Harper* also applied to incompetent pretrial detainees who posed a risk of harm and were

refusing treatment. This again demonstrated the federal courts' deference to clinical decision makers in determining treatment needs (though these cases also focused on the overarching institutional safety needs in their reasoning).

Some state courts have been willing to find greater rights for committed patients than the minimum set by the federal courts. In doing so, these courts have found that state law—statutes, common law, or state constitutions—provides additional protections beyond those mandated by the U.S. Constitution (Perlin 1993; Appelbaum 1994).

In a more recent twist on treatment refusal, the U.S. Supreme Court, in *Sell v. U.S.* (2003), also established parameters for overriding treatment refusal for the purpose of restoring an incompetent defendant's competence to stand trial. This case stands out not as reflective of a treatment-driven orientation, but it does focus on both a defendant's right to be competent when tried for a criminal matter, as well as the state's right to force treatment in order to expedite a trial process, though only in limited circumstances when a defendant is refusing treatment that would be necessary to ensure his or her competence to stand trial. The Court opined that treaters should look to alternative approaches to address treatment refusal (e.g., *Washington v. Harper* standards, local guardianship standards, etc.) before relying on the governmental interest in forcing treatment to ensure the defendant's competence to stand trial as the rationale.

Impact of the choice of model

There are several roles that the forensic psychiatrist may be called on to play with respect to the right to refuse treatment. As noted previously, the laws regulating treatment refusal and override of refusal vary based on jurisdiction, type of facility, and the legal status of the individual refusing treatment (e.g., a committed patient or a prisoner, a pretrial detainee, or an incompetent-to-stand-trial defendant); forensic psychiatrists may perform a vital function in educating treating psychiatrists about these laws. Forensic psychiatrists also may be called upon to act as consultants to treating psychiatrists in managing patients seeking to have their refusal upheld. Alternatively, forensic psychiatrists may be called on to act as expert evaluators for the individual's attorneys, hospitals, jails, prisons, or the court. Finally, psychiatrists knowledgeable about treatment refusal may be called on to help formulate policies and procedures for their hospitals, correctional facilities, and states. Because a forensic psychiatrist may assume a variety of roles with respect to a treatment-refusing patient, it is important to understand the data reflecting the impact of the choice of the model for overriding treatment decisions.

The rates of psychotropic medication refusal can range from 2% to 44% across all settings, with some studies estimating significantly higher rates of treatment refusal in forensic settings (Owiti and Bowers 2011) (though most available data are from civil settings). In nonforensic settings, studies have shown that only approximately 10% of patients will refuse treatment with antipsychotics at some point during inpatient hospitalization, with certain variations depending on patient mix (voluntary or involuntary) and other factors (Hoge et al. 1990; Appelbaum 1994; Kasper et al. 1997; Owiti and Bowers 2011). Of those patients who refused medications in civil settings, between 50% and 90% refused treatment for less than 1 week. Reasons patients cite for ultimately agreeing to medication include prior experience and discomfort with court hearings; belief that the hospital will succeed in court; pressure from family to take medication; and belief that taking medication will result in a shorter hospital stay (Russ and John 2013).

When treatment refusal is persistent (which occurs in only a very small percentage of cases), empirical reports from various jurisdictions indicate that, regardless of the model employed (rights-driven or treatment-driven), the outcome of review is the same: treatment refusal is overturned in 90%–95% of cases (Appelbaum and Hoge 1986). Although a few studies showed that override of refusal may be less frequent in treatment-driven systems (Appelbaum 1994), a study of patients in a treatment-driven jurisdiction found that treatment refusal lasted only 2.8 days, and all patients who persistently refused treatment were ultimately treated involuntarily (Kasper et al. 1997). In contrast, Hoge et al. (1990) found that, in a rights-driven setting, refusal episodes lasted about 13 days, while 23% of treatment refusers had not been treated by the end of the study period. Approximately 18% of treatment refusers were brought before a court, a venue in which their refusal was consistently overturned. That most treatment refusals that go before a decision-making body (i.e., the courts or an administrative-type review) are overturned is undoubtedly due in part to the deference to clinical opinion shown even in rights-driven, judicial models of review. Yet, one cannot conclude from these data that the model of review has no impact on practice.

Earlier studies from jurisdictions with rights-driven models of review requiring judicial determination reported considerable delays and costs in obtaining hearings, an outcome that had been feared when these models were promulgated (Veliz and James 1987; Hoge et al. 1990; Schouten and Gutheil 1990). These delays contribute to the increased length of stay seen with treatment refusers. During the interval between refusal and judicial review, refusing patients can disrupt the treatment setting, thereby impairing the quality of other patients' treatment. Although restraint prevention is more robust than when some of these studies emerged, Hoge et al. (1990) found that treatment-refusing patients required seclusion and restraint with greater frequency than other patients, a finding that was consistent with a more recent review of several related studies (Owiti and Bowers 2011).

On the other hand, judicial review mechanisms—perhaps because they are so procedurally cumbersome—seem to empower patients. For example, as described above, in one jurisdiction with a rights-driven model, only a small fraction of treatment refusers were taken to review. The

majority of patients in this prospective study began to comply with treatment after some period of negotiation and discussion. In some cases, patients were successful in having the dosages of medication reduced. Nearly one-quarter of the patients had their medication discontinued, although in several cases this occurred in conjunction with discharge from the hospital (Hoge et al. 1990). It seems fair to conclude that rights-driven, judicial review does promote autonomy interests, although optimal treatment for refusing patients and fellow patients may be more readily compromised, and considerable financial expense will be incurred as a result.

Treatment-driven models of review may offer clear advantages in efficiency and clinical flexibility (Schouten and Gutheil 1990; Bloom et al. 1997). The informal procedures associated with treatment-driven models permit significantly more refusing patients to be reviewed. Although treatment-refusing patients in treatment-driven settings are just as likely to present with behavioral challenges as those in rights-driven settings, lengths of refusals may be shorter and reviews may be conducted more quickly, potentially leading to more rapid treatment and shorter hospital stays (Kasper et al. 1997).

Efficiencies gained by treatment-driven models of review may, however, come with some costs. Easy access to review may reduce some of the incentive for treating clinicians to negotiate with refusing patients and to thoroughly evaluate their concerns about medications. Treatment-driven models are also, by definition, not designed primarily to promote patient rights, and there has been concern that patients, when given less of a right to present their side to a neutral party, may not be as accepting of the outcome (Winick 1997, 384). Patients may feel that they do not have sufficient voice in a clinician-dominated process (Monahan et al. 1995). These are not necessary consequences of a treatment-driven model of review, but clinicians operating under such systems must be careful to consider the perspectives of refusing patients and to treat them with respect.

Patients who require court-ordered medication are at an increased risk for medication nonadherence after discharge, as well as for having treatment-resistant illness (Russ and John 2013). This future refusal may be related to the nature of the illness itself, symptoms of the individual's refusing treatment, or the fact that a person who refused medications once may also refuse them in the future (rather than a direct result of having had a prior court proceeding). A review of studies examining coercion in treatment and subsequent adherence to treatment found that longer-term adherence may be independent of whether coercion occurred at a certain point in time in treatment, though providing information to patients and treating patients fairly when there is a need to override their refusal often can reduce perceptions of coercion and enhance adherence (Pinals and Mossman 2012).

Psychiatric advance directives (PADs) and joint crisis plans (JCPs) are recently developed instruments that serve as vehicles whereby patients can express their views of what treatment they may or may not want to receive if they are unable to assert their preferences in the future (Campbell and Kisely 2009; Khazaal et al. 2014). In *Hargrave v. Vermont* (2003), the Second Circuit Court of Appeals found that a Vermont state law that permitted the override of durable powers of attorney, such as psychiatric advanced directives, in order to force treatment of civilly committed patients, violated the Americans with Disabilities Act. Although only applicable to Vermont and New York, the ruling raised the possibility that treatment refusal is considered an absolute right if appropriately asserted as a preference when competent. A recent study showed that, even when psychiatric advance directives are in place, there are circumstances in which clinicians still feel it is appropriate to override the patient's expressed advance wishes, especially in emergencies, when there is high risk of violence, and when the patient demonstrates lack of insight (Swanson et al. 2007). Other studies show that clinicians have more positive attitudes about PADs when they understand their provisions and limits (Elbogen et al. 2006). More research on and experience with PADs in clinical practice is needed to fully understand the impact of these tools.

GENERAL POINTS OF ASSESSMENT

Reasons for refusal

The reasons for treatment refusal must be assessed carefully. In many instances, patients' refusals of medication are based on actual side effects or other real concerns about their treatment (Owiti and Bowers 2011). Even common and relatively benign side effects, such as dry mouth and blurring of vision, which seem trivial in comparison with the beneficial effects of the medications, may lead to treatment refusal. It is necessary for clinicians to explore the practical impact and the meaning that patients impart to these side effects. Blurred vision, for example, may impair highly valued activities, such as reading or watching television. Patients also may ascribe dire meanings to the medications themselves or their side effects, which they may be reluctant to discuss with treating psychiatrists (Hoge et al. 1990; Appelbaum and Gutheil 2007; Owiti and Bowers 2011). In addition, patients may fear a loss of autonomy and pain from long-acting injectable medication (Jaeger and Rossler 2010).

Certain side effects warrant special mention. Patients may express their experience of akathisia and akinesia in idiosyncratic ways that potentially could be disregarded as being delusionally based. Some patients experience dysphoric responses to antipsychotic medication, which may lead to refusal. Many patients are embarrassed to discuss sexual dysfunction related to psychotropic medications, such as impotence, decreased libido, and retrograde ejaculation. Specific inquiry into the reasons behind treatment refusal is a necessary step before resorting to legal or administrative procedures to override the refusal (Appelbaum and Gutheil 2007).

Side effects rarely should be the basis of long-term treatmentrefusal.Variouspsychopharmacologicalmaneuvers—for

example, changing the type of antipsychotic or other psychotropic medication, dosage amounts and intervals, or adjunctive treatments—usually will ameliorate side effects. In many cases, a careful explanation of what the patient may expect with those changes may alleviate his or her concerns. Persistent treatment refusal related to side effects may be more likely when the risk–benefit ratio is narrow; for example, when a patient with significant tardive dyskinesia and a history of poor response to neuroleptics refuses medication that the treating psychiatrist thinks would be beneficial. With the introduction of newer medications, clinicians and patients have a wider range of options from which to choose in order to minimize side effects and maximize treatment opportunities (Pinals and Buckley 1999).

Treatment refusal is often illness related. Patients may refuse antipsychotic medication because of denial of their illness. Some patients will present with delusions about treatment and medication; for example, patients may believe that the medication is actually a poison. Perhaps not surprisingly, patients with less insight into their disease have higher rates of medication refusal (Droulout et al. 2003; Russ and John 2013).

Patients with illness-based reasons for refusing treatment pose the greatest clinical challenges. Even when psychiatrists, nurses, inpatient unit staff, family, and friends are intensively involved and united in support of medication, many of these patients will report that they have accepted medication only as a way to expedite discharge, and not because they have accepted an illness-based need for treatment (Hoge et al. 1990; Russ and John 2013).

Context of refusal

Methods for assessing and managing the treatment refuser may be gleaned from the context in which refusal takes place. For example, in an inpatient setting, the majority of patients who refuse medication do so shortly after admission (Hoge et al. 1990; Kasper et al. 1997). There may be many reasons for this; often, patients disagree about the need for hospitalization. Empathy, time, and space to adjust to hospitalization, along with motivational interviewing techniques and other strategies for engagement and shared decision making to foster patient-centered care, may lead to a quick end to treatment refusal (Laakso 2012).

Later in the course of hospitalization, more stable or long-term patients may refuse medication in response to specific problems on the unit or in the hospital. Patients may develop a distrust of staff. Less verbal patients may refuse treatment as a stereotypic response to physical or social distress. Finally, treatment refusal may reflect transference issues or other interpersonal difficulties. Therefore, the assessment of treatment refusal requires the broadest possible understanding of the patient's clinical circumstances (Wettstein 1999; Appelbaum and Gutheil 2007). Treatment refusal is very much context driven. The issues for the patient may be illness specific (e.g., refusal due to an eating disorder, a paranoid belief system, or a substance use disorder) and may require focused approaches that consider these issues in order to maximize treatment adherence.

Other contextual settings of treatment refusal have gained increasing attention. For example, some jurisdictions have adopted models of outpatient involuntary commitment, which often requires treatment compliance as a condition of maintaining outpatient status. This form of treatment is designed to target the issue of treatment refusal among civil outpatients and to prevent recurrent hospitalizations (Miller 1999; see also Chapter 15).

Clinicians working in correctional and forensic settings are faced with other challenges. For example and as previously noted, a pretrial defendant's right to refuse treatment has come under increasing legal and clinical scrutiny. The 1992 case of *Riggins v. Nevada* (1992) provided that treatment could be administered over the objections of a pretrial defendant only when "medically appropriate" and with "an overriding justification" for its administration. More recently in *Loughner* (2012), the Ninth Circuit Court of Appeals relied on *Harper* (1990) to help establish the mechanisms for any treatment override for pretrial defendants. As noted previously, *Sell v. United States* (2003) laid out criteria required to forcefully medicate a defendant for restoration of trial competence (see also Chapter 28). Treatment refusal by an inmate on death row who is then incompetent to be executed raises a host of other issues that are beyond the scope of this chapter but are covered in Chapter 57. Regardless of the context, clinicians working with treatment-refusing patients should consider the principles outlined above when managing such refusals and also understand any relevant case law that impacts practice. Developing a strong therapeutic alliance with the patient and an understanding of the patient's rationale for refusal may be the treating clinician's best approach.

Competence assessment

In those jurisdictions with rights-based models, careful assessment of competence to refuse medications is necessary (see Chapter 14 for a general discussion of this topic). Although most jurisdictions recognize a lack of understanding of a proposed treatment as determinative of incompetence, frequent impairments of competence will be related to deficiencies in patients' abilities to express sustained choices, rationally manipulate information, and appreciate the nature of their problem. With regard to treatment refusal, many patients who refuse treatment are likely to do so because they do not believe that they have a mental illness (Appelbaum and Hoge 1986; Hoge et al. 1990; Appelbaum and Gutheil 2007).

Appropriateness of treatment

When acting as a consultant, either to the treating psychiatrist or to the patient, the forensic psychiatrist must make

an independent determination of the appropriateness of the prescribed treatment. Many episodes of refusal occur among acutely psychotic, newly admitted patients, and treatment is frequently appropriate in this clinical context. However, not all clinical scenarios are this unambiguous, and concerns about the appropriateness of treatment will increase as the risk–benefit ratio narrows. Proper evaluation requires careful attention to history, diagnosis, and assessment of psychopathology and side effects.

It is useful to begin with a thorough review of the records and history of the patient. Often, there will be a history of treatment with psychotropic medications. Documented evidence of the patient's previous response to treatment—in either past or current hospitalizations—should be carefully reviewed. Ideally, such a review will allow for a correlation between symptoms and various medication trials. Consulting psychiatrists should establish the patient's diagnosis and contributing variables that may impact treatment refusal (e.g., communication styles and deficits, cognitive limitations, etc.). The ultimate diagnosis will depend on the review of available records and the diagnostic interview. In some instances, further testing or information gathering may be necessary. Signs and symptoms of mental illness should be assessed, described, and documented carefully.

An essential component of the evaluation is the assessment of any potentially significant side effects, such as abnormal involuntary movements or metabolic syndrome. Structured instruments, such as the Abnormal Involuntary Movement Scale (AIMS), and requisite laboratory analyses should be utilized when available to assist in the quantification and documentation of side effects. Subjective complaints should be elicited and explored as described above.

Substituted judgment

In jurisdictions that rely on a substituted judgment standard for determining whether or not incompetent patients will receive antipsychotic medications, psychiatrists must look for evidence of their patient's treatment wishes when competent. Jurisdictional case law may spell out specific factors for review (e.g., *Rogers v. Commissioner of Mental Health*). In many cases, the best indication will be the patient's record of adherence to treatment during periods of wellness or times of improved functioning. Advance directives, if they exist, should be reviewed. Family members, friends, and previous inpatient and outpatient psychiatrists are also good sources of information. Understanding any potential religious objections to treatment also will be important. In jurisdictions that require the substituted judgment standard, sophisticated and careful psychiatrists will document competence assessments and medication adherence of their patients during well periods. Such documentation may prove particularly valuable in the event of a later refusal of treatment (Appelbaum and Gutheil 2007).

Reasoning process

In formulating the approach to a particular patient who is declining treatment, the dialogue with the patient must be placed in the broader and longitudinal context of the patient's treatment as a whole. Because most treatment—even for individuals who decline treatment at some point in the course of their illness—will primarily be voluntary in nature, and because interactions with physicians can play an important role in illness management, it is important to engage the patient to help understand the treatment refusal in practice. Viewing treatment refusal merely as a legal obstacle to be surmounted as quickly as possible is a common error for treating psychiatrists. The management of an episode of treatment refusal requires the varied skills of the psychiatrist: psychopharmacology, psychological management of the therapeutic alliance, and management of the milieu. Psychiatrists must not allow their feelings about the law get in the way of their acting in the best interest of the patient; indeed, many psychiatrists find legal regulation of the right to refuse treatment to be a significant intrusion into clinical matters. Although legal proceedings can create a whole host of new responsibilities and additional effort, they should not be taken lightly. Regardless of the necessity of legal or administrative proceedings, treatment refusal may be an opportunity to strengthen the treatment bond, particularly if handled with an appropriate level of engagement of, and discussion with, the patient (Appelbaum and Gutheil 2007).

When a patient is refusing treatment, ultimately, three options exist: (1) negotiation and dialogue, (2) discharge, or (3) pursuit of an override of the patient's refusal.

Negotiation and dialogue

Treatment refusal should be viewed initially as an invitation by the patient to engage in a dialogue and negotiate treatment. The psychiatrist will explore the reasons for refusal and its context. Depending on the outcome of this initial interaction, one of two questions needs to be addressed:

1. Can the patient arrive at an individualized and personal decision that will allow acceptance of the prescribed medication?
2. Are there reasonable accommodations that the treating psychiatrist can make to foster adherence?

When a patient refuses a proposed treatment, the treating psychiatrist should make an effort to engage the patient and to help him or her accept either the proposed treatment or a reasonable alternative upon which the patient and the psychiatrist agree (Patel et al. 2008). Depending on the context and staff available, the efforts of the psychiatrist should be augmented by those of the nursing and milieu staff; family members and other loved ones are also important in making efforts to help patients understand why the

proposed treatment may be beneficial to them. It can be helpful to focus on how adherence to medication can help the individual achieve his or her specific goals. Strategies to engage individuals without focusing only on the medication issues can be very helpful in building trust and fostering an alliance with the patient.

Clinicians should guard against becoming entrenched in their positions regarding treatment. When doctor-patient relationships become contentious, it is important to take a step back and consider using techniques such as shared decision making and self-directed care to work with patients (Patel et al. 2008). Nevertheless, at times communications break down, and the physician and the patient may find themselves in a power struggle. Outside consultation may be helpful in navigating past such impasses. Through exploration, the treating psychiatrist may find ways to address patients' concerns about medication. Clarification of misconceptions, frank discussion of side effects, and a consistent posture of seeking to act in the best interest of the patient provide the necessary foundation for resolution. Even if the psychiatrist is unable to elicit voluntary treatment adherence in one particular instance, this approach offers the greatest promise for long-term clinical success (Appelbaum and Gutheil 2007).

Discharge

Discharge "against medical advice" may be considered in some cases when negotiation fails. This term is used more commonly in medical settings but can also be used in psychiatric settings. Clinicians may determine that it is preferable to respect the wishes of the patient rather than to pursue override of refusal. In some instances, there will be little choice. Patients who are competent (in those jurisdictions in which override of refusal requires a determination of incompetence) may be discharged or provided with other types of therapies if they are determined not to pose an unreasonable risk to themselves or others.

Discharge from the hospital should not be a rejection of the patient or an abandonment of treatment. The team should inform the patient that follow-up care, including but not limited to treatment with medication, is indicated and available (Appelbaum and Gutheil 2007).

Use of formal mechanisms to pursue override

In many instances, it will be impossible to negotiate a safe and reasonable medication regimen from a psychiatric perspective, and discharge will not be possible because of the patient's clinical condition (assuming the patient still meets criteria for commitment, appears to have significant deficits in competent decision making, or both). In general, groups of patients who are unlikely to proceed with voluntary treatment include those with very negative attitudes toward treatment and those who do not appreciate their clinical condition (Hoge et al. 1990).

Once the treating psychiatrist decides to seek override of the patient's refusal, the patient should be informed of this decision and the reasons for it. The procedures governing the review of the refusal should be explained fully, and the patient should be encouraged to participate in the process. To the extent possible, clinicians should discuss with patients what might be said about them during any adversarial proceeding. In some jurisdictions, patients will have been warned from the outset that their communications during an inpatient psychiatric hospitalization will not be confidential, to the extent that such communications are relevant to the judicial determination of treatment refusal override. For some patients, the process of adjudication can be made more therapeutic and less coercive if patients are given a mechanism by which to express their thoughts (Winick 1997, 342–344).

As mentioned previously, in the majority of cases that are formally reviewed, the refusal will be overturned. After such a ruling, patients should have the reasons for this judgment explained to them. In most instances, patients will accept medication at this point, and involuntary administration of medication will be unnecessary. An earlier study by Schwartz et al. (1988) affirmed this notion, as they found that the majority of patients who received involuntary medication eventually came to accept medication voluntarily and to acknowledge the need for treatment. Clinical experience has shown that even when medication is only available in oral forms, once an official determination to override treatment refusal has been made, many patients will no longer refuse the proposed medication. In jurisdictions that designate a decision maker on behalf of the patient (a guardian in most instances), the treating psychiatrist should obtain informed consent from this person, just as he or she would from a competent patient. Although it is not legally necessary to then obtain consent from the patient, it is desirable to continue to engage the patient in his or her treatment to the greatest possible extent, thus maintaining the therapeutic alliance. As in all clinical care, patient wishes about treatment should continue to be respected, where such wishes are reasonable and safe.

SUMMARY

Treatment refusal can be based on a number of factors. Psychiatrists must be aware of the legal mechanisms in their jurisdiction that permit the override of this refusal. At the same time, psychiatrists should continue working with patients to maximize their therapeutic alliance and subsequently improve their patients' adherence to their prescribed medication regimens. A strong working knowledge of the reasons for the treatment refusal, along with any relevant contextual factors, can be helpful in fostering discussions with patients addressing the treatment refusal.

SUMMARY KEY POINTS

- The currently recognized "right to refuse treatment" was refined in the last quarter of the twentieth century by developments in mental health case law, the evolution of the informed consent doctrine, and public perception about the quality of care delivered in psychiatric institutions.
- Legal approaches to the adjudication of treatment refusal fall into two models: rights-driven and treatment-driven (see Table 18.1).
- Reasons for refusal can be varied and may include actual side effects or other legitimate concerns about the treatment, denial of illness, or delusions about the medication.
- Goals for working with treatment-refusing patients include developing a strong therapeutic alliance, developing an understanding of the patient's rationale for refusal, and using shared-decision-making techniques in order to reach an agreement about treatment.

Confidentiality and testimonial privilege

ERIC Y. DROGIN AND KYLE C. WALKER

INTRODUCTION

Confidentiality and testimonial privilege are critical factors in both psychotherapy and mental health assessment alike. Perhaps no other juxtaposition of concepts better represents the delicate interplay of clinical and legal issues that makes forensic psychiatry among the most conceptually challenging of the medical specialties. Although these two terms address what at times may seem like indistinguishable treatment of the same sensitive information, confidentiality is an essentially ethical notion, while testimonial privilege is an essentially procedural one.

This distinction is reflected in the guidance attorneys obtain from the authoritative *Black's Law Dictionary* (ed. Garner 2014), which defines "confidentiality" as "the trusting relation between two people who have an especially close bond—as between lawyer and client, guardian and ward, or spouses—with regard to the faith that is placed in the one by the other" (p. 361), and defines "testimonial privilege" as "a right not to testify based on a claim of privilege; a privilege overrides a witness's duty to disclose matters within the witness's knowledge, whether at trial or by deposition" (p. 1391). Lawyers understand—or are supposed to understand—that confidentiality is the physician's broad duty to the patient, while testimonial privilege is the way that duty is expressed in a legal forum.

Similar guidance can be gleaned from decisions rendered by the appellate courts that determine how these distinctions are applied in actual legal practice. For example, in the Ninth Circuit Court of Appeals case of *United States v. Chase* (2003), the court maintained that "confidentiality" refers to "the broad blanket of privacy" that the state sees fit to place over "the psychotherapist–patient relationship," and "testimonial privilege" refers to "the specific right of a patient to prevent the psychotherapist from testifying in court" (p. 982). Just as the courts draw distinctions, so too do they establish connections. In the New Jersey Supreme Court case of *State v. Mauti* (2012), the court confirmed the generally held principle that testimonial privilege "may be waived implicitly where a party puts a confidential communication in issue" (pp. 1223–1224).

Statutes and regulations—embodying the codified laws that the appellate courts are sometimes called on to interpret—provide concrete rules for doctors to follow and for attorneys to apply. By way of illustration, when it comes to "confidentiality" (201 KY. Admin. Regs. 9:005 2015) the state of Kentucky defers to whatever standards the American Medical Association recommends—underscoring once more the extent to which the law concedes that this is an essentially ethical concern—while defining the corresponding testimonial "privilege" as the patient's right "to refuse to disclose and to prevent any other person from disclosing" a collection of "confidential communications" made for various purposes (KY. R. Evid. 507(b), 2015).

Such deference to the medical profession's perspective on confidentiality underscores the law's tacit acknowledgement that attorneys are essentially interpreters as opposed to architects of this notion. The frequently cited *Campbell's Psychiatric Dictionary* (2004) identifies "confidentiality" as "one element of the right of the patient to privacy," and specifies that "disclosure of information gained within the therapeutic relationship without the permission of the patient is a breach of confidentiality" (p. 144). Perhaps tellingly, this same source notes "privileged communication" is information that "the physician is not allowed to divulge… without the patient's consent" (p. 521), but does not attempt to distinguish it from confidentiality in terms of its having any particularly "legal" significance.

Forensic psychiatrists encounter and accommodate the related constructs of confidentiality and testimonial privilege with every patient they treat, with every examination they conduct, with every consultation they undertake, with every record they review, with every report they write, and with every opinion they express in depositions or on the witness stand at trial. Achieving the delicate professional balance these situations require calls for mastery of the evolving clinical, ethical, and legal considerations that surface at every turn in court-related practice.

In this chapter, we examine the codified ethical guidance as well as statutory provisions and exceptions, analyzing each of these sources in a stepwise fashion with additional reference to pertinent case law and the medico-legal professional literature.

CODIFIED ETHICAL GUIDANCE

The principles of medical ethics

The Principles of Medical Ethics with Annotations Especially Applicable to Psychiatry (American Psychiatric Association 2013) was designed to address "special ethical problems in psychiatric practice that differ in coloring and degree from ethical problems in other branches of medical practice" (p. 1). Perhaps nowhere are such differences more prominent and impactful than when they concern issues of confidentiality and testimonial privilege. Even when the guidance the *Principles* offers on both topics does not directly involve court-related activities, every provision is clearly relevant to the roles and obligations of the forensic psychiatrist.

Section 4 of the *Principles* mandates generally that "a physician shall respect the rights of patients, colleagues, and other health professionals, and shall safeguard patient confidences and privacy within the constraints of the law" (p. 2).

This broad, initial treatment draws an interesting distinction between "confidences" and "privacy." If "confidences" are best regarded as discrete disclosures offered by the patient to the doctor, then distinguishing them from "privacy" encourages us to bear in mind that the latter covers such other aspects of the patient's overall medical record as diagnoses, consultations, behavioral observations, personal circumstances, and documentation generated by third parties. Simply put, it is not just the "confidences" that are likely to be confidential, and potentially there is much that could wind up being barred from disclosure in a court of law based on testimonial privilege.

The exhortation that the psychiatrist's obligation is to "safeguard" this information "within the constraints of the law" is open to variable interpretations. The most conservative view would be that the psychiatrist should not *defy* the law when attempting to preserve a patient's confidences and privacy. An attorney, judge, or licensing board might, however, read Section 4 as requiring a degree of zealous advocacy for the patient's rights that compels the psychiatrist to exhaust all antidisclosure options that lie within the *limits* of the law. Less likely, but not unimaginable, is the prospect that Section 4 will be read as being limited to those situations that the law actually *addresses*.

To date, only two appellate decisions have directly addressed the "safeguarding" obligation described in Section 4 of the *Principles*. In *Crescenzo v. Crane* (2002), the Superior Court of New Jersey referred to this portion of Section 4 as a source of guidance that would "limit a physician's ability simply to disgorge privileged records as a result of a third-party subpoena" (p. 290). In *Seebold v. Prison Health Services, Inc.* (2012), the Supreme Court of Pennsylvania mentioned in passing—in fact, only in a footnote—that a brief in this case had cited Section 4 in support of the notion that "there are many scenarios in which informing individuals who are potentially at risk of an inmate's condition would violate the inmate's privacy rights and/or the physician's ethical duty to hold personal information obtained in the doctor/patient relationship in confidence" (p. 1241). Neither of these cases provides much insight into potential interpretations of the energy and fervor with which a psychiatrist must advocate for preserving confidentiality or for preventing testimony-based disclosure in the course of legal proceedings.

Each section of the *Principles* is embellished with a number of specially crafted annotations. Perhaps not surprisingly, Section 4 has twice as many of these—14 in all—than any other section. The annotations that are specifically relevant to confidentiality and testimonial privilege (pp. 6–7) are reproduced here with our own accompanying analysis:

> Psychiatric records, including even the identification of a person as a patient, must be protected with extreme care. Confidentiality is essential to psychiatric treatment. This is based in part on the special nature of psychiatric therapy as well as on the traditional ethical relationship between physician and patient. Growing concern regarding the civil rights of patients and the possible adverse effects of computerization, duplication equipment, and data banks makes the dissemination of confidential information an increasing hazard. Because of the sensitive and private nature of the information with which the psychiatrist deals, he or she must be circumspect in the information that he or she chooses to disclose to others about a patient. The welfare of the patient must be a continuing consideration. (p. 6)

This "extreme care" provision sets a high standard, but one that hardly could be characterized as inappropriate, because the emotional, legal, and material damages that could be suffered are potentially incalculable. The "essential" nature of confidentiality to psychiatric treatment has been recognized by the legal and medical professions alike, most prominently in the case of *Jaffee v. Redmond* (1996), in which the Supreme Court of the United States, recognizing that "50 States and the District of Columbia have enacted into law some form of psychotherapist privilege" (p. 12), and observing that "the mere possibility of disclosure may impede development of the confidential relationship necessary for successful treatment" (p. 10), ultimately held that this privilege should apply in federal courts as well.

The notion of a "growing concern regarding the civil rights of patients" is a bit of an anachronism, as this has been a primary focus of mental health commentators for decades (e.g., Szasz 1962; Appelbaum 1995), but an emphasis

on "the possible adverse effects" of various technological advances in data storage and sharing is as timely as it is well-placed. One of the most detailed sources for addressing the perils associated with such procedures is the American Psychological Association's "Record Keeping Guidelines" which are designed to "elaborate and provide assistance to psychologists as they attempt to establish their own record keeping policies and procedures" (2007, p. 993), in a fashion every bit as applicable to the needs of psychiatrists as to those of any other mental health professionals.

> A psychiatrist may release confidential information only with the authorization of the patient or under proper legal compulsion. The continuing duty of the psychiatrist to protect the patient includes fully apprising him/her of the connotations of waiving the privilege of privacy. This may become an issue when the patient is being investigated by a government agency, is applying for a position, or is involved in legal action. The same principles apply to the release of information concerning treatment to medical departments of government agencies, business organizations, labor unions, and insurance companies. Information gained in confidence about patients seen in student health services should not be released without the students' explicit permission. (p. 6)

The Health Insurance Portability and Accountability Act's (HIPAA; 45 CFR §164.500 et seq. 2000) mandates affect in a direct fashion what the "psychiatrist may release." As Shuman (2010) observed, "the limits of judicial discovery of protected health information are neither absent nor absolute in the forensic context" (p. 52), such that psychiatrists would do well to conduct their usual HIPAA-friendly notification procedures even when concluding that in some aspects this statute might not apply (Connell and Koocher 2003).

The "continuing duty" cited here should be seen not just as one that is projected into the future, but also as one that should have been formalized during the very earliest stages of the doctor–patient or doctor–examinee relationship. No section in these *Principles* truly enshrines and conveys the psychiatrist's obligation to establish and reinforce the service recipient's confidentiality rights at regular intervals. It is important to afford all parties an opportunity to plan ahead as psychotherapy or evaluations progress—the "connotations of waiving the privilege of privacy" must be understood from the outset, particularly when "legal action" is contemplated. It is here that the specter of testimonial privilege emerges in Section 4 for the first time. The reference to "patients seen in student health services" is somewhat reminiscent of another concern that for some reason garners no direct attention in the *Principles*—confidentiality in the supervision of medical students, residents, and other supervisees (eds. Ullmer et al. 2009).

According to the *Opinions of the Ethics Committee on the Principles of Medical Ethics with Annotations Especially Applicable to Psychiatry* (American Psychiatric Association 2016), confidentiality safeguards extend beyond the death of the patient, with an understanding that "weakening this view reduces our responsibilities to living patients who trust us to protect their confidences even after their death," and that "this is no less so if the deceased is a prominent person" (p. 26). Devotees of psychiatric history will recognize in this latter observation a reflection of the so-called "Goldwater Rule," adopted after psychiatrists were invited some five decades ago to opine in a magazine about the mental health condition of a presidential candidate (Friedman 2011).

> Clinical and other materials used in teaching and writing must be adequately disguised in order to preserve the anonymity of the individuals involved. (American Psychiatric Association 2013, 6)

This annotation does not specify whether any sort of informed consent procedure is presumed to have been undertaken with the "individuals" involved. The admonition that materials be "disguised" presumably refers to the names of the "individuals" in question, via the use of pseudonyms. Of course, another option would be to avoid any use of names whatsoever. Styling these persons as "individuals" (instead of, e.g., "patients") has a tendency to broaden—whether intentionally or not—the potential pool of persons to whom confidentiality protections are being extended.

According to the *Opinions of the Ethics Committee on the Principles of Medical Ethics with Annotations Especially Applicable to Psychiatry* (American Psychiatric Association 2016), the privacy of "persons other than the patient" who may appear in a training video "must be protected to the same degree as that of the patient" (p. 25).

Third-party considerations become particularly relevant to the forensic psychiatrist when one considers the increasing emphasis placed on the contributions of collateral sources of information in both criminal and civil cases (Kalmbach and Lyons 2006; Gold et al. 2008). Additionally—and perhaps somewhat ironically—the expansive language in this annotation serves as a reminder of the potential for *erosion* of confidentiality protections for patients, as determined on a state-by-state basis, when third parties are present during group or individual treatment (American Bar Association Commission on Domestic Violence 2007). Conducting some seminar teaching in the context of "peer review" may afford additional protections with respect to both confidentiality and testimonial privilege (Kohlberg 2002; Sharifi 2009):

> The ethical responsibility of maintaining confidentiality holds equally for the consultations in which the patient may not have been present and in which the consultee was not a physician. In such instances, the physician consultant should

> alert the consultee to his or her duty of confidentiality. (American Psychiatric Association 2013, 6)

This annotation, arguably the most ambiguously drafted piece of guidance to be found in the *Principles*, could be interpreted as asserting that it is every bit as important to maintain confidentiality when patients are not present as it is when the consultee is not a physician. Another plausible interpretation would be that in those situations in which patients are not present *and* the consultee is not a physician, psychiatrists must recognize that they bear the same confidentiality burdens as they do under the various other circumstances described in Section 4. In any event, forensic psychiatrists are best advised to maximize their commitment to confidentiality no matter which of these admonitions was actually intended. It remains unclear whether the "consultee" in this situation is the person to whom the psychiatrist is *providing* information, the person from whom the physician is obtaining information, or both. As a practical matter, it is better for forensic psychiatrists to take the broadest, most overtly patient-focused perspective and to assume that this guidance addresses both situations.

Puzzlingly, psychiatrists are being told to "alert the consultee to his or her duty of confidentiality." If "his or her" refers to the consultee, what duty truly exists for a nonphysician individual? If "his or her" refers to the psychiatrist, what is the purpose of this alert? Is it to provide some sort of reassurance that shared confidences are likely to go no further, perhaps with the goal of encouraging fuller and more detailed disclosure to the psychiatrist? Once more, the best course of action will be the one that lays out all potential obligations—those arguable as well as those established—to maximize protections and promote transparency when feasible.

> Ethically, the psychiatrist may disclose only that information which is relevant to a given situation. He or she should avoid offering speculation as fact. Sensitive information such as an individual's sexual orientation or fantasy material is usually unnecessary. (American Psychiatric Association 2013, 6)

"May" here surely means "shall." Some latitude will undoubtedly exist should the relevance in question subsequently be challenged by a licensing board or professional guild organization. For one thing, "relevant" is a legal term that does not necessarily comport with lay or other professional interpretations (Soltis et al. 2014). For another, the psychiatrist can hardly be expected to know how broadly cast is the "situation" in question—or what "situations" are likely to arise in the future. The psychiatrist's need to "avoid offering speculation as fact" is really a matter of professionalism that has little to do with confidentiality or testimonial capacity *per se*.

A murkier notion is the guidance Section 4 offers concerning "sensitive information." It is true that "sexual orientation" and "fantasy material" are "usually unnecessary." However, as a more general matter—for which sexual orientation and fantasy are offered merely as examples—"sensitive information" is as apt a way as any to describe a psychiatric patient's file and everything therein. It would have been more to the point simply to identify sexual orientation and fantasy as content either unworthy of documentation or destined for only brief mention, in light of concerns having to do with inappropriate or unforeseeably wider distribution.

> Psychiatrists are often asked to examine individuals for security purposes, to determine suitability for various jobs, and to determine legal competence. The psychiatrist must fully describe the nature and purpose and lack of confidentiality of the examination to the examinee at the beginning of the examination. (American Psychiatric Association 2013, 7)

These characterizations of various roles filled by psychiatrists—in particular by forensic psychiatrists—provide useful examples that enable doctors to place such duties in context. Specifying by way of follow-up comment that psychiatrists need to describe the "lack of confidentiality" at the outset of this particular type of examination may send an unintended message that *other* evaluative efforts do not merit similar warnings. In addition and as noted above, what remains missing is a sense that confidentiality should be revisited at critical junctures *during* the course of a forensic psychiatric evaluation—an exercise that may consist of multiple "examinations."

Because information gleaned from, and opinions generated related to, the types of services designated in this annotation are likely to be headed to the courtroom—especially concerning "legal competence"—it is worth considering discussing testimonial privilege (and the lack thereof) during these recommended descriptions. The "nature and purpose and lack of confidentiality of the examination" could refer to the nature of the examination, the purpose of the examination, and the examination's lack of confidentiality, or it could refer instead to the nature of the examination's confidentiality, the purpose of the examination's confidentiality, and the extent of the examination's lack of confidentiality. The latter approach is surely the safest, avoiding the incomplete and potentially misleading characterization of the "lack of confidentiality" as an absolute notion (e.g., "You need to know, of course, that there *is* no confidentiality").

> Careful judgment must be exercised by the psychiatrist in order to include, when appropriate, the parents or guardian in the treatment of a minor. At the same time, the psychiatrist must assure the minor proper confidentiality. (American Psychiatric Association 2013, 7)

This annotation appears to advise psychiatrists that the decision of whether or not to include parents or guardians in the treatment of children is a difficult one that merits special consideration. Conveying the "proper confidentiality" to a minor patient will require attention to two overlapping considerations: what is appropriate for the child—and to the extent relevant, for the family—for psychotherapeutic purposes, and what strictures the law provides. These limitations are jurisdiction-specific and take into account such factors as the child's age, the nature of the medical problems prompting clinical attention, and each state's construction of testimonial privilege for juvenile service recipients (Paruch 2009; Boumil et al. 2012). Semantics may have an important role to play in this passage should a psychiatrist ever be held to account for an alleged transgression: "assure" would mean that the doctor would provide the patient with information intended to underscore confidentiality rights, while "ensure" would mean that the doctor would take affirmative steps—perhaps after, as well as during treatment—to make certain that confidentiality is never breached.

> When, in the clinical judgment of the treating psychiatrist, the risk of danger is deemed to be significant, the psychiatrist may reveal confidential information disclosed by the patient. (American Psychiatric Association 2013, 7)

This brief annotation refers to circumstances that are arguably the most fraught with personal and professional danger. It alludes to the classic "duty to warn" or "duty to protect" notion most notably reflected in the Supreme Court of California case of *Tarasoff v. Regents of the University of California* (1976) and covered in detail elsewhere in this book.

The passing reference here to the "treating psychiatrist" begs the question of what sort of obligation the evaluating *forensic* psychiatrist might have—recently highlighted by the California Court of Appeal case of *Elijah W. v. Superior Court of Los Angeles County* (2013)—for mandatory reporting in the context of court-related assessment. The ruling in *Elijah W.* that the examinee "was entitled to the appointment of therapist who agreed to disclose information regarding child abuse, neglect, or threats only to minor's attorney" (p. 606) was narrowly jurisdiction-specific and cannot be relied on by doctors in other parts of the country. Given the unsettled nature of this issue, forensic psychiatrists are advised to sort out such concerns with counsel prior to the provision of services, and to make the agreed-upon conclusion a part of the informed consent process in each individual case.

> When the psychiatrist is ordered by the court to reveal the confidences entrusted to him/her by patients, he or she may comply or he/she may ethically hold the right to dissent within the framework of the law. When the psychiatrist is in doubt, the right of the patient to confidentiality and, by extension, to unimpaired treatment should be given priority. The psychiatrist should reserve the right to raise the question of adequate need for disclosure. In the event that the necessity for legal disclosure is demonstrated by the court, the psychiatrist may request the right to disclosure of only that information which is relevant to the legal question at hand. (American Psychiatric Association 2013, 7)

The clarity and salience of this annotation are perhaps unequaled not only in Section 4, but in the balance of the *Principles*. Outlined here is a logical, reasonable, and laudably patient-focused approach to navigating between the twin perils of psychotherapeutic betrayal and legal sanction. Consulting with retaining counsel in order to anticipate such concerns may make it considerably easier to establish and maintain the contemplated lines of communication with the court as successive levels of engagement are encountered (Drogin and Barrett 2013).

> With regard for the person's dignity and privacy and with truly informed consent, it is ethical to present a patient to a scientific gathering if the confidentiality of the presentation is understood and accepted by the audience. (American Psychiatric Association 2013, 7)

Unlike those situations in which courtroom involvement is predicted, the anticipation of an eventual presentation to a "scientific gathering" is not one for which the psychiatrist is expected to seek informed consent at the outset of service provision. Indeed, this is actually inadvisable when one considers the unintended "grooming" effect that this foreknowledge could have on the nature and course of psychotherapy. Perhaps more to the point than "understanding" and "acceptance" on the part of the audience is some affirmative action on its part to "ensure" confidentiality—even if this merely involves, for example, affixing one's name to a sign-up sheet that is circulated prior to the confidential portion of the presentation in question.

It is worth noting that a "scientific gathering" may be attended by numerous laypersons—not just students, assistants, and professional guild organization staff, but in some cases members of the press. Additionally, some presentations are recorded, often with pay-per-view options tied to Continuing Medical Education (CME) credit. Will the subsequently distributed material be accompanied by sufficient confidentiality warnings and attestation requirements? Such concerns should be considered well in advance of the presentation.

> It is ethical to present a patient or former patient to a public gathering or to the news media only if the patient is fully informed of enduring loss of confidentiality, is competent, and consents in writing without coercion. (American Psychiatric Association 2013, 7)

This annotation raises concerns essentially similar to the preceding concern, with a few interesting twists. For one, competency and a lack of coercion are surely no less relevant with respect to a "scientific gathering" than they would be to a "public gathering" or in the context of some sort of print or broadcast media event. These attributes should be ensured in each of these situations. Also, the "patient or former patient" designation here contrasts with the more basic "patient" designation employed in the preceding annotation. Presumably there is no reason to assume that a "former" patient (or, in particular, examinee) would not be entitled to the same treatment as a current one when a "scientific gathering" is contemplated—particularly when forensic psychiatric material is being presented (cases in which litigation is still pending are often unsuitable for such presentations). This is due not only to the examinee's interest in the outcome of court proceedings, but also counsel's interest—on the examinee's behalf—that upcoming expert witness testimony not be aired prematurely.

> When involved in funded research, the ethical psychiatrist will advise human subjects of the funding source, retain his or her freedom to reveal data and results, and follow all appropriate and current guidelines relative to human subject protection. (American Psychiatric Association 2013, 7)

Confidentiality and, to a much lesser extent, testimonial privilege issues are significant considerations in the conduct of clinical and forensic psychiatric research. The fact that they receive relatively minimal coverage in mainstream ethical codes is not a sign of disregard but instead a tacit acknowledgement of an increasingly narrow delineation of academic and practice roles. "Appropriate and current guidelines" for this topic include the *American College of Physicians Ethics Manual* (American College of Physicians Ethics, Professionalism, and Human Rights Committee 2012), which provides substantial attention to a full range of research-oriented concerns.

Ethical guidelines for the practice of forensic psychiatry

As indicated above, a forensic psychiatrist benefits from mastery of the contents of the *Principles* even when they do not directly address legal matters *per se*. There is, however, another highly regarded and oft-noted source of ethical guidance concerning confidentiality (though not testimonial privilege) that is tailor made for the concerns of the civil or criminal expert witness. The American Academy of Psychiatry and the Law (AAPL) has promulgated *Ethics Guidelines for the Practice of Forensic Psychiatry* (2005), Section II of which includes the following treatment of "Confidentiality":

> Respect for the individual's right of privacy and the maintenance of confidentiality should be major concerns when performing forensic evaluations. Psychiatrists should maintain confidentiality to the extent possible, given the legal context. Special attention should be paid to the evaluee's understanding of medical confidentiality. A forensic evaluation requires notice to the evaluee and to collateral sources of reasonably anticipated limitations on confidentiality. Information or reports derived from a forensic evaluation are subject to the rules of confidentiality that apply to the particular evaluation, and any disclosure should be restricted accordingly. (p. 1)

Here, forensic psychiatrists are informed in a crisp and accessible fashion that they should pay attention to confidentiality, that they should do all that they can with regard to whatever legal rules apply, that they should make sure that the persons they evaluate understand confidentiality and its limitations, and that the by-products of an evaluation should be kept as confidential as the evaluation itself. Use of the wording "to the extent possible" places a rather substantial burden on forensic psychiatrists, as someone seeking to turn the *Guidelines* against them could simply argue that there was *something* the doctor could legally have done that he or she did *not* attempt to do. To date, no federal or state appellate decisions have referred to Section II.

The guidance in Section II of the *Guidelines* is amplified by a "Commentary" section, reproduced here in its entirety with our own accompanying analysis:

> The practice of forensic psychiatry often presents significant problems regarding confidentiality. Psychiatrists should be aware of and alert to those issues of privacy and confidentiality presented by the particular forensic situation. Notice of reasonably anticipated limitations to confidentiality should be given to evaluees, third parties, and other appropriate individuals. (p. 1)

Although the "significant problems" this sort of work entails are not enumerated here, they are easy enough to identify. On the one hand, the very *lack* of confidentiality inherent in forensic psychiatric evaluation often makes it difficult to elicit valid and useful information when evaluees understand how their disclosures may ultimately be used against them. They may become intimidated to the point of dissimulation that seemingly resembles malingering (Rogers 2008). On the other hand, evaluees who *fail* to grasp this circumstance may become resentful and uncooperative in later stages of the process when they eventually realize—too late—that their testing and interview responses have a potentially lengthy and toxic shelf life, as addressed by the next portion of this "Commentary":

> Psychiatrists should indicate for whom they are conducting the examination and what they will do with the information obtained. At the

> beginning of a forensic evaluation, care should be taken to explicitly inform the evaluee that the psychiatrist is not the evaluee's "doctor." Psychiatrists have a continuing obligation to be sensitive to the fact that although a warning has been given, the evaluee may develop the belief that there is a treatment relationship. Psychiatrists should take precautions to ensure that they do not release confidential information to unauthorized persons. (pp. 1–2)

This guidance pinpoints the "continuing" need for confidentiality education in a fashion that is decidedly lacking in the text of the aforementioned *Principles*. The skillful forensic psychiatrist is often a seasoned psychotherapist whose clinical mien may coax the evaluee into a sense that treatment is being provided—particularly when the doctor has been sent by the evaluee's lawyer and touted as the special individual who can provide a way out of the evaluee's current legal morass. This role distinction often can be eroded by the forensic psychiatrist's ill-advised willingness to provide treatment *after* the fact, or to accept a forensic assignment when he or she was the evaluee's doctor *previously* (Strasburger et al. 1997; Drogin 2012):

> When a patient is involved in parole, probation, conditional release, or in other custodial or mandatory settings, psychiatrists should be clear about limitations on confidentiality in the treatment relationship and ensure that these limitations are communicated to the patient. Psychiatrists should be familiar with the institutional policies regarding confidentiality. When no policy exists, psychiatrists should attempt to clarify these matters with the institutional authorities and develop working guidelines. (American Academy of Psychiatry and the Law 2005, 2)

In the professional literature, relatively little attention is paid to the unique challenges that accompany forensic treatment—for example, situations in which the state forensic hospital, having determined that an evaluee was incompetent to stand trial, is now tasked with competency "restoration" on the basis of a combination of psychotherapy and medication (Samuel and Michals 2011). Under these circumstances, the advice proffered earlier by this Commentary—that one must avoid fostering "the belief that there is a treatment relationship"—is essentially stood on its head, in recognition of the simple realities of the intersection of law and medicine; however, a logically based, stepwise method of working through potential conflicts is outlined here.

STATUTORY PROVISIONS AND EXCEPTIONS

For better or for worse, American jurisprudence plays out across a panoply of 51 different state and federal jurisdictions. Fortunately, when it comes to statutory guidance, there is a broad commonality of themes, because of the similarity of issues that psychiatrists face regardless of the State in which they practice. Following is a typical example—Hawaii's "Physician–Patient Privilege" (HI.R. Evid. 504 2013), with our accompanying analysis of its various components:

1. Definitions. As used in this rule:
   a. A "patient" is a person who consults or is examined or interviewed by a physician.
   b. A "physician" is a person authorized, or reasonably believed by the patient to be authorized, to practice medicine in any state or nation.

      The "patient" and "physician" in this scheme are defined as broadly as possible. The "believed by" concept is typical of such statutes, because it would not be fair for the patient to have his or her information subject to disclosure because of a simple error in identity—particularly when one considers the parade of variously credentialed individuals the patient typically would encounter in a general or psychiatric hospital setting.
   c. A communication is "confidential" if not intended to be disclosed to third persons other than those present to further the interest of the patient in the consultation, examination, or interview, or persons reasonably necessary for the transmission of the communication, or persons who are participating in the diagnosis and treatment under the direction of the physician, including members of the patient's family.

      The key provision here is actually "intended." This reflects once again an understanding that "confidentiality" is an essentially ethical notion controlled by rules ingrained in medicine, as opposed to the law. Communications still can remain confidential when they move beyond the physician–patient dyad, as long as this comports with the overall context of treatment. For example, if a psychiatrist discusses the patient's medication with the patient's spouse, who will make sure the proper dosage is administered at the correct time, this discussion should not cause details of the patient's medical care to no longer be protected.
2. General rule of privilege. A patient has a privilege to refuse to disclose and to prevent any other person from disclosing confidential communications made for the purpose of diagnosis or treatment of the patient's physical, mental, or emotional condition, including alcohol or drug addiction, among oneself, the patient's physician, and persons who are participating in the diagnosis or treatment under the direction of the physician, including members of the patient's family.

   What was "intended" to be confidential is now safe from disclosure in the context of civil or criminal legal proceedings. The patient does not have to divulge this information in court and can keep the doctor from doing so as well. The broadly inclusive language ensures

that virtually everyone normally expected to witness medically oriented disclosures will be covered.

3. Who may claim the privilege. The privilege may be claimed by the patient, the patient's guardian or conservator, or the personal representative of a deceased patient. The person who was the physician at the time of the communication is presumed to have authority to claim the privilege but only on behalf of the patient.
4. This is a critically important point in testimonial privilege. The privilege exists for the purpose of protecting patients, making it a foregone conclusion that they—or their representatives—are the ones who should be enabled to invoke it. Because doctors are the individuals most likely to have the relevant information in their possession, it seems logical and saves time for them to "claim" the privilege as well, but they are really only doing so in the patient's stead. Therefore, a better term would actually be "assert" the privilege. Exceptions include the following:
   a. Proceedings for hospitalization. There is no privilege under this rule for communications relevant to an issue in proceedings to hospitalize the patient for mental illness or substance abuse, or in proceedings for the discharge or release of a patient previously hospitalized for mental illness or substance abuse.

      This commonsensical provision is directly relevant to the day-to-day duties of clinical and forensic psychiatrists alike. Because the substance of civil commitment proceedings requires initial or at least eventual judicial oversight, raising a roadblock of testimonial privilege in these matters would be pointless.
   b. Examination by order of court. If the court orders an examination of the physical, mental, or emotional condition of a patient, whether a party or a witness, communications made in the course thereof are not privileged under this rule with respect to the particular purpose for which the examination is ordered unless the court orders otherwise.

      Forensic psychiatry gets its due here; the doctor's role is acknowledged as directly as possible. A close reading of this provision telegraphs what are essentially the "exceptions to the exception," as disclosures must pertain to a "particular purpose." For example, in the course of an examination to determine competency to stand trial, defendants may admit to having committed the crime in question. In the context of civil proceedings in a personal injury matter, plaintiffs may refer to some aspect of their private lives that would unduly prejudice a jury without having relevance to the case under consideration. A court could reasonably exclude such information.
   c. Condition an element of claim or defense. There is no privilege under this rule as to a communication relevant to the physical, mental, or emotional condition of the patient in any proceeding in which the patient relies on the condition as an element of the patient's claim or defense or, after the patient's death, in any proceeding in which any party relies on the condition as an element of the party's claim or defense.

      Seizing further on the above-noted notion of what may be the "particular purpose" of certain legal proceedings, this provision sets out in no uncertain terms the logically compelling perspective that if the patient needs to use this information, it will not be privileged. Interestingly, despite postmortem confidentiality concerns addressed by the Ethics Committee of the American Psychiatric Association (2013), anyone whose legal case focuses on the condition of a deceased individual is likely to be able to have that information entered into evidence.
   d. Proceedings against physician. There is no privilege under this rule in any administrative or judicial proceeding in which the competency, practitioner's license, or practice of the physician is at issue, provided that the identifying data of the patients whose records are admitted into evidence shall be kept confidential unless waived by the patient. The administrative agency, board, or commission may close the proceeding to the public to protect the confidentiality of the patient.

      This provision negates the possibility that the physician could lay claim to a privilege that is essentially that of the patient. It also enables governmental agencies, acting in the public interest, to review patient files in order to identify a pattern of malpractice or other malfeasance that could result in the restriction or revocation of a doctor's license. A recent *cause célèbre* in this regard was the case of *Maryland Board of Physicians v. Eist* (2011), in which a psychiatrist was ultimately unable to prevent punishment by the Board for declining to release patient records in the context of contentious divorce and child custody proceedings.
   e. Furtherance of crime or tort. There is no privilege under this rule if the services of the physician were sought, obtained, or used to enable or aid anyone to commit or plan to commit what the patient knew or reasonably should have known to be a crime or tort.
   f. Prevention of crime or tort. There is no privilege under this rule as to a communication reflecting the patient's intent to commit a criminal or tortious act that the physician reasonably believes is likely to result in death or substantial bodily harm.

Public safety concerns are a predictable source of privilege exceptions. State authorities are naturally loath to enable convicted or suspected criminals to hide behind unjustly obtained advantages. Here, also, is a correlate of the aforementioned *Tarasoff* situation, in which doctors have complied with a "duty to warn" or "duty to protect." Prosecutors seeking criminal sanctions or plaintiffs' attorneys seeking

monetary compensation for their clients are allowed to introduce this sort of evidence despite its having been obtained from an otherwise protected medical record.

SUMMARY KEY POINTS

- Although they overlap in various theoretical and practical ways, confidentiality is an essentially ethical concern, while testimonial privilege is an essentially legal one.
- With respect to confidentiality, codified ethical guidance establishes that medical records must be protected with extreme care, that release of medical information requires formalized authorization, and that courts can compel release of this information on their own under certain circumstances, though the psychiatrist's professional obligations may include challenging such mandates within the limits of the law.
- Statutory provisions—confirmed by state and federal case law—provide for a testimonial privilege that may be claimed by the patient, or by the psychiatrist on the patient's behalf, concerning confidential communications that occur between the psychiatrist, the patient, and a select group of persons whose participation typically enhances diagnosis or treatment.
- A number of exceptions to testimonial privilege exist, typically regarding such subject matter as proceedings for involuntary hospitalization, court-ordered evaluations, conditions that constitute an element of a patient's legal claim or defense, and lawsuits or complaints filed against psychiatrists.

The duty to protect

ALAN R. FELTHOUS AND CLAUDIA KACHIGIAN

INTRODUCTION

Psychiatrists and other mental health professionals can, under certain circumstances, be liable in a malpractice claim when a patient seriously harms another person. The consulting forensic psychiatrist must be familiar with relevant legal cases, statutory law, and the professional standard of practice regarding his or her duty to protect nonpatient third parties.

Depending on jurisdictional law, psychiatrists' duty to protect can necessitate risk assessments to serve three different protective mechanisms, all of which are intended to reduce the risk of the patient's killing or seriously harming another person: assessment to determine whether (1) hospitalization, involuntary if not voluntary; (2) protective disclosures or warnings; or (3) reporting in compliance with gun control law, respectively, are indicated.

These three protective legal requirements for mental health professionals developed sequentially. The duty to control and protect by hospitalization was in place "pre-*Tarasoff*." *Tarasoff*-like warnings and reportings became legal duties in many states through both common and legislative law, following the first law of its kind, the Supreme Court of California's "*Tarasoff* principle" of 1976. Recently, gun control legislation, already in effect for decades, has been expanded in a small number of states to further restrict firearm possession by mental patients deemed to be dangerous.

TARASOFF AND ITS PROGENY CASES

According to common law in the United States, one person, such as a psychiatrist or psychotherapist, is not responsible for the harmful violence that a second person, such as a patient, inflicts upon a third person, unless the first person had a special or controlling relationship with either the second or the third person (Restatement [Second] of Torts 1965). Hospital administrators and physicians were thought to have considerable control over patients and were sometimes held accountable for discharge decisions that resulted in adverse outcomes. As hospital care became more restricted in favor of community treatment programs, however, the prospect of treating outpatients who were mentally ill and potentially violent became more commonplace.

In 1974, the Supreme Court of California, in its *Tarasoff I* decision, articulated the duty to warn (*Tarasoff v. Regents of the University of California* 1974, 559). As a result of the decision, therapists in California had a legal duty to notify an identifiable victim and/or the police when a patient presented a danger of seriously harming another person and when such disclosures were the most reasonable measures to prevent violence. Several organizations, including the American Psychiatric Association, criticized this new case law (Brief of Amicus Curiae in support for Rehearing of Tarasoff 1975), so the Court reheard the case. The second decision, *Tarasoff II* (hereafter designated *Tarasoff*), in 1976, vacated *Tarasoff I*, replacing its "duty to warn" with a "duty to protect," which emphasized warnings but also allowed for other protective actions.

Through its 1976 *Tarasoff* decision, the Supreme Court of California extended liability to the world of outpatient care and, more explicitly than before, articulated a therapist's duty to protect third persons through the formulation known as the *Tarasoff* principle:

> When a psychotherapist determines, or pursuant to the standards of his profession should determine, that his patient presents a serious danger of violence to another, he incurs an obligation to use reasonable care to protect the intended victim against such danger. The discharge of this duty may require the therapist to take one or more of various steps, depending on the nature of the case. Thus, it may call for him to warn the intended victim or others likely to apprise the victim of the danger, to notify the police, or to take whatever other steps are reasonably necessary under the circumstances. (p. 431)

The *Tarasoff* decision created responsibilities and liabilities for therapists who have little actual control over their patients. In some instances, the principle could pertain

to patients who could not be civilly committed. Although *Tarasoff* is the most widely known case on the duty to protect, many other courts subsequently addressed the issue of protecting third persons.

Four evolutionary periods in the clinicians' duty to warn or protect since the mid-twentieth century are recognized. In the pre-*Tarasoff* period *(1950–1974)*, any duty to protect third persons derived from a duty to control the potentially violent patient, typically through hospitalization.

More extensive liability to third persons was generally limited by (1) the nonresponsibility rule; (2) sovereign immunity; (3) the honest error in professional judgment rule (Felthous 1987); and (4) the "firefighter's rule."

In the pre-*Tarasoff* period, the common law rule of nonresponsibility was more protective against third-party liability. Clinicians were not liable for a patient's violent acts against others unless the patient was negligently discharged or poorly supervised and negligently allowed to escape from the hospital (Felthous 1987). The common law rule of nonresponsibility and its specific exceptions that permitted liability were formulated in the Restatement (Second) of Torts by the American Law Institute in 1965.

The exception most applicable to a hospital patient, especially civilly committed, was the *custodial relationship* in Section 320 that was defined by *control*:

> One who is required by law to take or who voluntarily takes the custody of another under circumstances such as to deprive the other person of his normal power of self-protection or to subject him to association with persons likely to harm him, is under a duty to exercise reasonable care so to control the conduct of [these] persons as to prevent them from intentionally harming others or so conducting themselves as to create an unreasonable risk of harm to him, if the actor:
>
> - Knows or has reason to know that he has the ability to control the conduct of the [other] person, and
> - Knows or should know of the necessity and opportunity for exercising such control.
>
> (Restatement [Second] of Torts, Section 320 1965)

Further supporting the importance of the element of control in the relationship was the *takes charge* exception to nonresponsibility of Section 319:

> One who takes charge of a … person whom he knows or should know to be likely to cause bodily harm to others if not controlled is under a duty to exercise reasonable care to control the … person to prevent him from doing such harm.
> (Restatement [Second] of Torts, Section 319 1965)

Courts consistently followed the common law rule of nonresponsibility and the takes-charge exception during the pre-*Tarasoff* period. Regardless of how "special" an outpatient relationship might have been considered, liability for violent harm inflicted on third persons could occur where the patient was controlled through hospitalization, but not through outpatient treatment (Felthous and Kachigian 2001a).

Sovereign immunity provided the second source of protection against liability for the violent harm that a patient inflicts on another. A species known as judicial immunity bars a party in a lawsuit for suing the court for an adverse judgment, and similarly, one cannot sue the government for a policy decision that resulted in harm. Because decisions to control or release a hospitalized patient were considered discretionary, a person who is injured by a discharged patient could not sue the hospital or the government clinician who discharged the patient. The clinician's inability to accurately predict future violence was implicitly respected through the recognition of the fallibility of decisions over the safe management of mental patients (Felthous and Kachigian 2001a).

Even in the pre-*Tarasoff* period, sovereign immunity was not equally protective of government clinicians in all jurisdictions. In order to ensure that victims of negligence by government employees have equal access to redress and compensation as victims of negligence in the private sector, Congress enacted the Federal Tort Claims Act (FTCA) (28 U.S.C.A. Sec. 2671) (West 1990). Some courts found clinicians' decisions to discharge to be discretionary and therefore nonliable (e.g., *McDowell v. County of Alameda* 1979), whereas others regarded such decisions as ministerial, involving "implementation of policies or regulations, and accordingly liable within the FTCA" (e.g., *Fair v. United States* 1956; *Merchants National Bank & Trust Co. of Fargo v. United States* 1967). Nonetheless, sovereign immunity provided protection against third-party liability, especially in the pre-*Tarasoff* period, but even since then in some jurisdictions (e.g., *Canon v. Thumudo* 1988).

The honest error in professional judgment rule (e.g., *Greenberg v. Barbour* 1971) provided the third pillar of protection of pre-*Tarasoff* immunity. Courts resisted sustaining liability where the only error was an honest mistake in professional judgment. For liability to exist there must have been negligence that exceeded a single, good-faith misjudgment. This principle was advanced in 1954 by the New York Appellate Court in *St. George v. State*. Other courts subsequently cited *St. George* when invoking the rule (Felthous and Kachigian 2001a).

Clinicians may not have such duty if the victim of the patient's threatened and actual violence happens to be a police officer or firefighter who was victimized while responding to an incident in the course of his or her employment (*Tilley v. Schulte* 1999). This is known as the "firefighter's rule." In the pre-*Tarasoff* period, no liability for a clinician's failure to warn a potential victim of a patient's violent threats was recognized.

The second evolutionary period was the *inception of the Tarasoff principle (1974–1980)*, wherein outpatient therapy was posited as providing enough "control" over a patient

so as to impose on the therapist a duty to warn or protect under the "takes charge" exception (Section 319 of the Restatement [Second] of Torts) of the common law rule of nonresponsibility (American Law Institute 1965).

Liability through failure to control by hospitalization was essentially eliminated by California's Lanterman–Petris–Short Act (LPS Act), California's progressive mental health code, which was signed into law in 1967 and became effective in 1972. LPS provided immunity for liability related to hospital admission and discharge decisions. In other words, in order to support the dehospitalization and community mental health movements, the California legislature negated the traditional basis for liability to third persons, failure to control through hospitalization. The Supreme Court of California in *Tarasoff* invoked the immunity provision of the LPS Act in dismissing the claim of failure to hospitalize, viz "to detain" a dangerous person. After other claims were consolidated or dismissed, the remaining claim was "failure to warn of a dangerous patient." The question before the court was how liability, no longer available for failure to control by hospitalization, could be found in outpatient treatment without considering hospitalization.

From its opinion, it is clear that the court relied heavily on the just published law review article by Fleming and Maximov (1974). From this article, the court found that enough "control" exists in an outpatient psychotherapeutic relationship for the "special relation" exception to the rule of nonresponsibility, heretofore allowing liability concerning decisions to initiate or continue hospitalization, to now allow for liability concerning a claim of failure to warn of the violent acts of an outpatient (Felthous 1989).

The *period of diversification (1980–1989)* was the third evolutionary period, when courts and state legislatures adopted a wide variety of rules concerning warnings to potential third persons about the acts of potentially violent patients. These rules included the foreseeability rule, the foreseeable victim rule, the identifiable victim rule, the specificity rule, the zone of danger rule, the sovereign immunity rule, and the professional judgment rule. Some courts, on the other hand, found no duty to warn or protect. If earlier psychiatrists anticipated that the *Tarasoff* principle would be adopted by their state, by the mid-1980s it became clear that they were required to familiarize themselves with the relevant law of their own state (Felthous and Kachigian 2001a).

The fourth evolutionary period was *Retreat from Tarasoff (1990–1999)*, when appellate courts and legislatures restricted application of the *Tarasoff* principle by the following means: adoption but with limitations, rejecting a duty to warn (e.g., in Florida [*Boynton v. Burgess* 1991]) and/or a duty to control a voluntary patient (e.g., Virginia [*Nasser v. Parker* 1995], and acknowledging a duty to warn or protect but proactively circumscribing its application (e.g., Illinois [*Charleston v. Larson* 1998]) (Felthous and Kachigian 2001a). The important point is that the consulting forensic psychiatrist must become familiar with the relevant case law of the jurisdiction in which treatment being examined was rendered.

LAW FROM THE LEGISLATURES

Thirty states now have statutes that explicitly permit or establish a duty for psychiatrists to make some type of disclosure to protect those threatened by their patients. Almost all of these statutes present options for dealing with patients posing a threat (Table 20.1). Most all the statutes allow or require warning the potential victims. Other options include informing law enforcement or hospitalizing the patient. Less common options include warning the parents of a minor or other state-specific alternatives. For example, in Arizona the duty can be fulfilled by "taking any other precautions that a reasonable and prudent mental health provider would take under the circumstances." Such a law implicitly acknowledges the uniqueness of each situation and gives significant discretion to individual clinicians, but it provides precious little more guidance than the courts have done.

The *Tarasoff* statutes fall into one of the following four categories with regard to whether they establish or affirm a duty to warn: those that (1) seem to explicitly establish a duty, (2) prohibit liability except under specified circumstances, (3) seem to be permissive, and (4) take other approaches. A statute that creates a duty includes wording such as "a mental health professional *has a duty*" (emphasis added). Conditional duties are evident from wording such as "There can be no cause of action … unless …" On the other hand, the language of permissive statutes appears to allow warning, without requiring protective disclosure (e.g., "The psychiatrist *may* disclose …") (Kachigian and Felthous 2004).

LAW FROM BOTH COURTS AND LEGISLATURES

A number of states now have *both* case and statutory law that address a *Tarasoff*-like duty to warn or protect. Familiarity with relevant case law alone is insufficient for the forensic psychiatrist who consults on a "duty to protect" case in one of these jurisdictions, as is examining only the state's protective disclosure statute. Germane law may have been crafted by both the legislature and the courts and may include law governing civil commitment and privileged and confidential information. Therefore, it behooves the consultant to be somewhat knowledgeable about both statutory and judicial law pertaining to confidentiality and the duty to protect.

Sponsors and originators of *Tarasoff*-inspired protective disclosure statutes hoped for greater clarity and coherence of the duty to protect within the state's jurisprudence. A systematic review of appellate court decisions in states with such statutes in place revealed remarkable diversity in how courts applied or chose not to apply the relevant statute in *Tarasoff*-like situations. Courts' use of *Tarasoff* statutes could be broadly classified as (1) not referencing the state's *Tarasoff* statute; (2) referencing the state's statute but not using it in the court's analysis; (3) referencing the statute, using it in the court's analysis, and finding that the statute creates a duty; (4) referencing the statute, using the statute in the court's

[a] Provide options for dealing with patient-expressed threats, but statute is permissive; no explicit duty to warn or protect is stated.
[b] Initiation of hospitalization unspecified as voluntary or involuntary.
[c] Acknowledgment of a *Tarasoff*-like warning included only as an exception to privileged communication.

analysis, but finding that the statute does not create a duty; and (5) referencing the statute only in the context of testimonial privilege (Kachigian and Felthous 2004).

In this review, only a minority of court decisions interpreted their state statute so as to delimit the clinician's duties owed to third parties. Most court decisions concerning *Tarasoff*-like situations left the duty to protect ambiguous, and either overlooked the statute or found a common law duty to override the statute's limitations. Thus, even in states with *Tarasoff* statutes, forensic psychiatrists must keep abreast of relevant common law that may or may not be consistent with or override the statute.

Although the survey by Kachigian and Felthous demonstrated the disparate court responses to *Tarasoff* statutes, two other surveys came to contrary conclusions. From their earlier survey, Herbert and Young (2003) further confirmed that the *Tarasoff* jurisprudence lacked coherence on a national level. In a follow-up article (2003), Herbert concluded that protective disclosure law has vitiated psychotherapy. In a more recent survey and in contrast, Soulier and colleagues (2010) found *Tarasoff*-like liability appeared to be reduced where *Tarasoff* statutes with an affirmative duty were in place. Fox (2010) provided reasons why the low *Tarasoff* liability may have been inflated. If such statutes provide risk management guidance to clinicians, the concern over diverse approaches taken in the common law remains valid. Even if always necessary, and usually helpful, comparisons of statutory and judicial law are not always satisfactorily clarifying, particularly because the process can be confounded by the flux of changing public policies. Here we cite only California as one of several possible comparisons.

If court responses to *Tarasoff* protective disclosure statutes represent a third generation of *Tarasoff* jurisprudence, California now has developed a fourth in the most recently enacted amendment to its original *Tarasoff* statute. The four generations are as follows: (1) the Supreme Court of California formulated its well-known duty to protect, with warnings serving as an option for fulfilling this duty; (2) California enacted its original *Tarasoff* protective disclosure law (Cal. Civ. Code §43.92 [1986]) intended to clarify when the duty to warn exists and how it is to be discharged; (3) the *Tilley v. Schulte* (1999) decision required warning of a threat without further risk assessment and the *Ewing* cases (*Ewing v. Northridge Hospital Medical* Center 2004; *Ewing v. Goldstein* 2004) interpreted the law to require automatic warnings, in effect eliminating a duty to protect; and (4) now the amended protective disclosure law restores the *Tarasoff* principle of protection, which may be fulfilled with, but not necessarily by, warnings (Cal. Civ. Code §43.92 [2013]).

The California *Tarasoff* statute was amended in 2013 to replace "duty to warn" with "duty to protect" (Section 13.92 of the California Civil Code 2013). As before, the statute

exempts a psychotherapist from the liability of her or his patient's violent behavior, "except if the patient has communicated to the psychotherapist a serious threat of physical violence against a reasonably identifiable victim or victims." Under these circumstances, there is no liability when the therapist "discharges his or her duty to protect by making reasonable efforts to communicate the threat to the victims or victims and to a law enforcement agency." The amended statute further specifies that the present amendments "only change the name of the duty referenced in this section from a duty to warn and protect to a duty to protect."

Weinstock et al. (2014) commend this current amended California *Tarasoff* statute that makes the duty solely one of protection, allowing the clinician more flexibility to make the optimal intervention in a particular case. Although notifying victims and police of the danger/threat may provide protection, clinicians can also take alternative, legally defensible measures, especially if the clinician has reason to believe that warnings could exacerbate the patient's risk. As an example, Weinstock et al. (2014) point to the *Ewing* case (*Ewing v. Goldstein* 2004; *Ewing v. Northridge Hospital Medical Center* 2004) wherein the treaters of the hospitalized daughter thought that if they warned her father that she wanted to kill him, he would more likely kill her after her discharge. In this case, it was thought the warning would increase rather than decrease the risk of someone being killed. In any event, the clinician is prudent to document the reasoned justification for her or his selected protective measure, whatever that measure might be.

The *Tarasoff* duty to protect of the Supreme Court of California was borne out of there being no duty to hospitalize, and the current *Tarasoff* statute does not establish an explicit duty to control by hospitalization. Unlike other states, California still provides immunity against liability for failure to hospitalize. Also unlike some other states, immunity for failure to protect does not inure by involuntary hospitalization of a dangerous patient in the State of California (Weinstock et al. 2014).

More complete chronologies of the evolution of the *Tarasoff* jurisprudence in California are provided by Weinstock et al. (2006, 2014).

DISTINGUISHING THE DUTY TO WARN FROM THE DUTY TO CONTROL

The *Tarasoff* Principle consolidated protective duties under a single "duty to protect." Many courts outside of California followed the Supreme Court of California's precedent in this respect. Eventually, other courts separated out a duty to warn from a duty to control, typically by extending hospitalization. Accurate understanding of a jurisdiction's jurisprudence over a clinician's protective duties requires close attention to this distinction, particularly where it delineates a clinician's obligation. Courts that have made this distinction have variously adopted and rejected a duty to warn. Courts have similarly adopted and rejected a duty to control (Felthous and Kachigian 2001b).

DOES THE DUTY TO WARN SAVE LIVES?

Soon after the Supreme Court of California's *Tarasoff* Decision, critics of this case law argued that it would endanger rather than protect others because potentially violent patients would be reluctant to enter therapy and those in therapy would hesitate to share their violent thoughts with their treatment provider (Stone 1976). In the years following *Tarasoff*, surveys of therapists provided some empirical support to these concerns (Wise 1978; Rosenhan et al. 1993). Other authors reported that legally required protective warnings have promoted the therapeutic alliance (Wulsin et al. 1983), resulted in therapists paying more attention to a patient's potential for violence and to carefully documenting (Buckner and Firestone 2000), and have not adversely affected the therapeutic relationship when warnings are discussed with the patient prior to their being made (Beck 1980). Perlin observed that "there is no reliable database of empirical evidence as to the therapeutic value of *Tarasoff* warnings or of the case's ultimate 'real life impact'" (Perlin 1992, 60). Slobogin (2006–2007) concluded that many jurisdictions have rejected a *Tarasoff*-like duty to warn because of such duties' lack of demonstrated value in reducing serious violent acts by patients.

Edwards (2010) used a fixed-effects model to examine differences in timing and duty to warn laws' relationship with intra-state rates of homicide. He concluded that "mandatory duty to warn laws cause an increase in homicides of 5%" (p. 1). A finding that homicide rates are higher in states with mandatory duty to warn laws does not prove, however, that warning identified victims or the mandatory warning laws actually cause patients or even nonpatients to commit homicide. Clearly, more research is needed to determine why states with mandatory reporting laws have higher rates of homicide, if indeed this is a replicable finding.

TYPES OF DUTY TO WARN

Four different warning practices that are based partly on the purpose and wording of the guiding law have been identified in the literature: (1) warning of the risk of violence, (2) warning of the threat of violence, (3) requested warning, and (4) criminal victims' warning mandated by statute (Felthous 2006). In "warning of the risk of violence," warning the identified potential victim is not automatically triggered by a verbal threat. Rather, the patient's verbal threat or other indication that the patient presents a risk of seriously harming another person causes the clinician to evaluate the patient further to determine whether, beyond the verbal threat itself, he or she presents an increased risk of harming the victim. Only if the clinician determines the risk to be elevated does the clinician then warn the victim of the risk, not simply the verbal threat. This is the model that is discussed and promoted in the literature and complies with the *Tarasoff* Principle (Felthous 2006), which specifies that it is the danger (not a verbal threat) that is to be disclosed.

Apart from the *Tarasoff* Principle, various *Tarasoff* statutes and court opinions do not mention risk assessment or communication of the risk. Rather, the clinician's duty appears to be triggered by the patient's expression of a verbal threat, and it is the threat, not the risk, that is to be communicated to the would-be victim. For example, although the *Tarasoff* Principle of the Supreme Court of California would mandate the would-be victim be notified of the "danger" (*Tarasoff v. Regents of the University of California* 1976, 426), until the most recent amendment to the statute, the subsequent *Tarasoff* statute would require that the victim be informed of the "threat" (Cal. Civil Code §43.92 [1986, 1970, 2013]).

The third practice is to warn a person who fears physical violence by the patient because the person requests to be warned. Typically, the requesting person was already threatened or assaulted by the patient and wants to be warned, not of the risk of violence or of any expressed threats, but that the patient is about to be released from custody, whether from a hospital, jail, or prison.

Although not legally relevant to a clinician's duty to warn or protect, clinicians, particularly those employed in a correctional or forensic institutional setting, should be aware of their state and the federal mechanism for notifying victims or witnesses upon release of an individual inmate. A person who has been criminally victimized by another can request to be notified when the offender is released from incarceration. Such notifications are made through correctional authorities or prosecutors immediately prior to the offender's release (Corcoran 2003). This is a matter of victim's rights and does not involve mental health clinicians or risk assessment (Felthous 2006).

MENTAL ILLNESS, GUNS, AND HOMICIDE

Every year, tens of thousands of people in the United States are killed with firearms. In the year 2010, 31,672 persons were killed with firearms. In 2011, 11,101 people committed homicide with firearms, a rate of 3.6 per 100,000. This represented a decrease from 2006 (12,791, 4.29 per 100,000). During this period, suicides by firearms increased from 16,883 (i.e., 5.66 per 100,000) to 19,766 (i.e., 6.3 per 100,000) (Alpers et al. 2015).

Although precise figures on the number of homicides committed by mentally ill persons with a firearm as the lethal weapon remain elusive, it appears that most homicides resulting in *Tarasoff* litigation and published legal cases involved firearms (Felthous 1989). In any event, to the extent that some may kill as a result of mental illness (Kunz et al. 2013), it seems reasonable to assume that more aggressive treatment of these individuals' mental disorders and close management would offer hope for preventing some of these homicides.

Federal and state legislatures have enacted successive laws intended to prevent criminal felons and mentally ill persons thought to be at risk for killing themselves or others from possessing firearms (see Khin Khin et al. 2013). In the wake of the horror ignited by mass killings, most recently the slaughter of children at the Sandy Hook Elementary School in Newtown, Connecticut, several states have extended this public policy to require mental health professionals to report to authorities mental patients who are thought to be at increased risk of gun violence (see Beck et al. 2013).

As of the writing of this chapter, the State of New York has the most expansive gun control law designed to keep those mentally ill persons thought to be at risk for violence from owning a gun (New York State Penal Law, Section 400.00, 11[6]; NYS Office of Mental Health, New York Mental Hygiene Law, Section 9.46; see NY Mental Hygiene Law, Section 9.01, NYS Office of Mental Health; Ollove 2013). As of 2013, mental health professionals are required to notify local officials of patients whom they deem "likely to engage in conduct that will cause serious harm to self or others." Because this reporting standard is consistent with the standard used for emergency hospital detention in New York, the law seems to trigger this reporting requirement whenever emergency hospitalization is initiated. Other states also have enacted reporting laws intended to dispossess of their firearms mentally ill persons thought to be at risk. Thoughtful analysis of such legislation and the ethics of psychiatric compliance with such regulations have been discussed and can be referenced for practice guidance.

Regardless of the gun control laws that exist in the state where one practices, inquiry should be made about possession of and access to firearms whenever a patient presents a risk of suicide or homicide. Even without reporting requirements such as those in New York, the clinician should initiate measures to ensure that firearms are securely removed from and inaccessible to a patient who is at risk for suicide or homicide. This can be accomplished with assistance from the patient's family or friends, law enforcement, and/or the patient.

ASSESSMENT OF THE RISK OF VIOLENCE TO A TARGETED INDIVIDUAL

As with assessment of risk for suicide, assessment of risk of violence toward others begins with the history of the present illness (e.g., recent violent thoughts, acts, and preparatory acts) and mental status examination (e.g., anger, hostility, resentment, and violent thoughts). If after initial assessment there is reason to be concerned about violence toward others, further assessment is in order. For purposes of this discussion, emphasis is placed on assessment of risk toward one or more targeted individuals, not the risk of violence in general, which is addressed in Section 7 of this book.

Felthous (1999) proposed an algorithm to help psychiatrists in dichotomous decision making for warnings and hospitalization as measures to prevent violence to third parties. This algorithm requires the psychiatrist to attempt to answer the following four questions: (1) Is the patient dangerous to others? (2) If yes, is the patient's dangerousness due to serious mental illness? (3) If not due to serious mental illness, is the dangerousness imminent? and (4) Are

potential victims of the patient's violence reasonably identifiable? We would add to these questions the importance of always asking a patient who has thought about homicide about firearm access. If the patient has firearm access, reasonable measures should be taken to make the firearm(s) inaccessible to the patient. Weinstock and colleagues (2014) would add additional questions related to determining whether warning the potential victim would increase the risk of violence.

Assessment of dangerousness is a dynamic process because dangerousness itself ebbs and flows with internal changes and interactions with the environment, which can include therapeutic and other interventions that are less intrusive than warnings and less restrictive than hospitalization. Protective intervention, like the prediction of violence, is more art than science; the critical question is whether an appropriate attempt was made at assessment and appropriate intervention.

The potential for homicide and serious assault can be evaluated much like suicide potential. There are many helpful writings on the clinical assessment and safe management of potentially violent patients. Forensic psychiatrists should be familiar with the recommendations in the literature for assessing the risk associated with verbal threat, but they must exercise caution in assigning new standards of practice with corresponding liability. Borum and Reddy (2001), for example, provide a reasoned approach for assessing a patient's threat to harm a specific person.

The psychiatric profession has not settled on a standard for warning victims and notifying police. Even the American Psychiatric Association's model code for protecting third parties does not advocate a duty to protect, much less a specific duty to warn, though this code lists warnings as one of the protective actions the psychiatrist might choose to select (Appelbaum et al. 1989). Warnings and reports have long been allowed by ethical standards designed to prevent violence but have not been ethically prescribed (American Psychiatric Association 1989). The expert may point to a legal duty to warn if it is prescribed by law. Otherwise, in jurisdictions where the duty is not yet firmly imposed, the expert who feels compelled to opine that a victim should have been warned probably should qualify this conclusion as the expert's own judgment and not insist that it is a practice to which most of the psychiatric profession would adhere. A failure to warn is more clearly in error if it is in violation of case or statutory law, rather than if it is a perceived deviation from a nonexistent clinical standard.

In many duty-to-protect cases, the most serious and patent errors are clinical ones, not the failure to take extra-clinical measures such as warning a victim and reporting to a law enforcement agency. For example, the potentially violent patient was not evaluated carefully, not diagnosed accurately, not admitted to the hospital, not medicated properly, not observed closely enough, or the patient was discharged from the hospital prematurely and without adequate planning.

CONSULTATION ON DUTY-TO-PROTECT CASES

The forensic psychiatrist who consults on duty-to-protect cases already should be familiar with landmark cases in duty to protect jurisprudence. Some knowledge of recent legislative trends and familiarity with writings of clinicians on the topics of evaluating and managing potentially violent patients, risk assessment (e.g., Simon and Tardiff 2008), and algorithmic decision making is useful. Finally, it is recommended that the consultant continue to treat violent patients and remain well-practiced in the field.

If the referral comes from another state, the forensic psychiatrist should enlist the referring attorney's assistance in procuring pertinent jurisdictional law from state and federal courts, any protective disclosure statute, any privileged and confidential information statutes, and the state's mental health code. If the clinician–defendant was employed by a hospital or institution, obtain policy statements pertaining to homicidal and violent patients. With regard to the instant case, obtain all medical and psychiatric records, transcriptions of all depositions and courtroom proceedings already held on the case, and all exhibits already submitted into evidence.

The consultant should have some basic questions in mind before starting to read the case materials. Was the clinical assessment adequate? Was the diagnosis appropriate? What, if any, signs of violent potential were there? If clinical findings warranted further assessment for violent potential, was this done? Was the treatment provided appropriate? If signs of violence were escalating, was hospitalization considered? If the patient was hospitalized, the consultant should assess information on the level of observation, control, and thoughtful discharge planning before releasing the patient. The presence of sufficient and accurate progress notes is always a consideration. Finally, the consultant must look for sufficient communication between treaters if several professionals have been involved in the patient's treatment.

Though relying on legal parameters, the consultant should endeavor to be more fair and practical than the law seems to be. Our colleagues can be sued for breach of confidentiality or for failure to warn or protect. If the stakes seem high for physicians, consider their patients and the patients' potential victims. Inappropriate disclosure of confidential information can cause a patient to lose a job or his or her most valued relationship. Failure to take preventive action may lead to homicide. Yet our abilities to accurately predict and prevent violence are extremely limited (Mossman 2010). The clinician walks on a precarious tightrope. Tilting to one side or the other can risk liability for oneself and harm others.

The fair consultant will grant the defendant some margin by which to exercise good-faith judgment before finding an error of committing a breach of confidence in the face of serious potential harm or of omitting such disclosure to take specific extra-clinical measures. Fault can be established more firmly where the defendant violated clear legal

regulations or deviated from the clinical standard of care. If the consultant is to refrain from advancing novel duties and standards, the prudent expert must also have the courage and objectivity to identify violations of a clearly stated and unambiguous law or substandard clinical practice, where the dereliction of the clinician's duty proximately caused the patient to harm another person.

SUMMARY KEY POINTS

- Embedded in the *Tarasoff* Principle duty to protect is the option of warning the intended victim of the serious danger, not necessarily a verbal threat.
- The duty to warn or protect in a given jurisdiction arises from the courts, the legislature, or both. These bodies not infrequently have disharmonious views about many aspects of this duty.
- It is not clear whether the legal duty to warn, as a component of the duty to protect, actually saves lives.
- Inquiry about access to firearms is a prudent measure when assessing and managing a patient's risk of violence.
- When consulting on a professional negligence case in which failure to fulfill the duty to protect is claimed, the forensic psychiatrist should check the relevant jurisdictional law from both statute(s) and court decisions.

Treatment boundaries in psychiatric practice and sexual misconduct in the therapist–patient relationship

ROBERT I. SIMON

INTRODUCTION

The concept of treatment boundaries developed during the twentieth century in the context of outpatient psychodynamic psychotherapy. Treatment boundary issues arose from the very beginning of psychoanalysis, reflected in Freud's disputes with Ferenczi, Reich, and others. Ethical principles promulgated by the mental health professions and the legal duties imposed by courts and statutes have additionally defined treatment boundaries. For example, the clinician's maintenance of confidentiality derives from three distinct duties: professional (clinical), ethical, and legal. Treatment boundaries are set by the therapist that define and secure the professional relationship of the therapist with the patient for the purpose of promoting a trusting, working alliance.

The boundary guidelines listed below are generally applicable across the broad spectrum of psychiatric treatments. Nevertheless, considerable disagreement exists among psychotherapists regarding what constitutes treatment boundary violations. Appropriate technique for one therapist may be considered a boundary violation by another therapist. Much variability in defining treatment boundaries appears to be a function of the nature of the patient, the therapist, the treatment, and the status of the therapeutic alliance. For example, notable exceptions may exist in alcohol and drug abuse programs, in inpatient settings, and with certain cognitive-behaviorally based therapies. Regardless of the therapy used, however, every therapist must maintain basic treatment boundaries with all patients. If boundary exceptions are made, they should be for the benefit of the patient. Every effort must be exerted to therapeutically restore breached boundaries. Brief boundary crossings that are quickly rectified can provide useful insight into conflictual issues for both the therapist and patient (Gutheil and Gabbard 1993). Harm threatens the patient when boundary violations progress in frequency and severity over time.

Boundary guidelines maintain the integrity of therapy and safeguard both the therapist and the patient. Proponents of therapies that breach generally accepted boundary guidelines risk harming the patient and incurring legal liability (Simon 1990a). Psychiatry continues to be highly receptive to innovative therapies that offer the hope of more effective treatments for the mentally ill (Simon 1993). The maintenance of basic treatment boundaries should not be inimical to therapeutic creativity.

With regard to sexual misconduct, the sexual exploitation of patients by therapists is of serious professional, ethical, and legal concern for the mental health professions. The results of a nationwide survey of psychiatrist–patient sex revealed that 7.1% of male and 3.1% of female respondents acknowledged sexual contact with their patients (Gartrell et al. 1986). Of the sexual contacts that occurred, 88% took place between male psychiatrists and female patients, 7.6% between male psychiatrists and male patients, 3.5% between female psychiatrists and male patients, and 1.4% between female psychiatrists and female patients. Most surveys show a consistent gender difference that varies from approximately 2:1–4:1 male-to-female ratio of therapists who sexually exploit their patients.

Survey results of sexual misconduct may be inaccurate because of underreporting related to embarrassment, fear of civil liability, and potential or pending criminal investigations. A 2004 review article (Sarkar 2004) on boundary violations stated, "It is also possible that sexual boundary violations, like other types of sexual misdemeanour are underreported because of issues to do with shame and guilt; and it is also possible that false accusations are comparatively overreported." Not utilizing survey results, and instead using literature review, individual state and government

agencies, Marshall et al. (2008) reported that "an estimated 6%–10% of psychiatrists have had inappropriate sexual relations with patients." It is difficult to report accurate current numbers regarding the incidence of sexual misconduct by mental health professionals because of the possible reporting issues mentioned above. Though the exact number of patients or therapists involved is not known with certainty, it is known that sexual misconduct by therapists unfortunately continues to occur.

PSYCHOTHERAPY: THE IMPOSSIBLE TASK

All psychiatric treatments, regardless of theoretical orientation, are based on the fundamental premise that the interaction with another human being can alleviate psychic distress, change behavior, and alter a person's perspective of the world (Simon and Sadoff 1992). Psychotherapy can be defined as the application of clinical knowledge and skill to a dynamic psychological interaction between two people for the purpose of alleviating mental and emotional suffering. This principle also applies to biological and behavioral therapies. Yet psychotherapy is an impossible task (Simon 1990a). There are no perfect therapies, and there are no perfect therapists.

Psychotherapy has been described as a mutually regressive relationship with shared tasks but different roles (Shapiro and Carr 1991). Boundary violations are therapist role violations that inevitably occur to some degree in every therapy. Although maintaining treatment boundaries is a major psychotherapeutic task, competent psychotherapy also requires recognition by the therapist that he or she has erred. Often, the work of psychotherapy involves the therapeutic restitution of breached boundaries. Treatment boundaries usually can be re-established if the therapist raises a boundary violation as a treatment issue. Because therapists use themselves as a primary therapeutic tool, sensitivity to boundary violations must be maintained at a high level.

From a clinical perspective, the therapeutic alliance is considered by many practitioners to be the single most critical factor associated with successful treatment (Marziali et al. 1981). The maintenance of treatment boundaries creates the foundation for the development of the therapeutic alliance and the subsequent work of therapy. Trust is the essential basis for a secure therapeutic relationship that permits patients to reveal their most intimate problems. The patient's trust is based on the conviction that the therapist will use professional skills in a manner that benefits the patient. The development of trust may be the sole treatment goal. The maintenance of consistent, stable, and enabling treatment boundaries creates a safe place for the patient to risk self-revelation. Fundamentally, the therapist's professional concern and respect for the patient ensure that treatment boundaries will be preserved.

Treatment boundary violations occur on a continuum, usually interfering with the provision of good clinical care to the patient. Boundary violations frequently result from the therapist's acting out of his or her personal conflicts. As a consequence, the patient's diagnosis may be missed or overlooked. Inappropriate or useless treatment may be rendered. Moreover, the patient's original psychiatric condition may be exacerbated.

BOUNDARY GUIDELINES

Treatment boundaries are established by the therapist according to accepted professional standards. It is the therapist's professional duty to set and maintain appropriate treatment boundaries in the provision of good clinical care. This duty cannot be relegated to the patient. Once treatment boundaries are established, *boundary* issues inevitably arise from the therapeutic work with the patient, and these form an essential aspect of treatment. *Boundary crossings* that arise from either the therapist or the patient are quickly addressed and rarely harm the patient (Gutheil and Gabbard 1993). *Boundary violations*, on the other hand, arise solely from the therapist and are often detrimental to treatment, particularly if unchecked and progressive. The therapist who creates idiosyncratic boundaries or sets no boundaries at all is likely to provide negligent treatment that harms the patient and invites a malpractice suit. A fundamental task for practitioners is the maintaining of constant vigilance against boundary violations and immediately repairing any breaches in a clinically supportive manner.

The following boundary guidelines for psychotherapy help maintain the integrity of the treatment process:

- Maintain relative therapist neutrality.
- Foster psychological separateness of patient.
- Protect confidentiality.
- Obtain informed consent for treatments and procedures.
- Interact verbally with patients.
- Ensure no previous, current, or future personal relationship with the patient.
- Minimize physical contact.
- Preserve relative anonymity of therapist.
- Establish a stable fee policy.
- Provide consistent, private, and professional setting.
- Define time and length of sessions.

Some of these basic guidelines have been considered by Langs (1990, 303–323) to form the necessary treatment frame for the conduct of psychodynamic psychotherapy. Although additional boundary rules could be elaborated, a general consensus exists concerning the basic rules listed above. For example, rules concerning the management of transference and countertransference could be included but might not find ready acceptance among some behaviorists, biological psychiatrists, and in "here and now" treatments such as Gestalt therapy. Nevertheless, all therapists, regardless of their theoretical orientation, must recognize that transference and countertransference play an important role in any therapy.

An absolutist position concerning boundary guidelines cannot be taken. Otherwise, it would be appropriate to refer to boundary guidelines as boundary standards. Treatment boundaries are not rigid, easily defined, static structures that separate the therapist from the patient like a wall. Instead, they delineate a fluctuating, reasonably neutral, safe space that enables the dynamic, psychological interaction between therapist and patient to unfold. Because treatment boundaries have a certain degree of flux, unanimity of professional opinion does not exist on a number of boundary matters. Moreover, clinicians may place greater emphasis on certain boundary guidelines.

UNDERLYING PRINCIPLES

Rule of abstinence

There are a number of fundamental, overlapping principles that form the bases for boundary guidelines. One of the foremost principles is the rule of abstinence that states that the therapist must refrain from obtaining personal gratification at the expense of the patient (Freud 1959). Extratherapeutic gratifications must be avoided by both therapist and patient (Langs 1990, 303–323).

A corollary of the rule of abstinence states that the therapist's primary source of personal gratification *derives* from professional involvement in the psychotherapeutic process and the satisfactions gained in helping the patient. The only material satisfaction directly obtained from the patient is the fee for the therapist's professional services. Treatment boundaries are violated when the therapist's primary source of gratification is received from the patient directly rather than through engagement in the therapeutic process with the patient. The rule of abstinence is fundamental to virtually all boundary guidelines.

Duty to neutrality

The rule of abstinence attempts to secure a position of neutrality for the therapist with the patient. Therapeutic neutrality is not defined in the psychoanalytic sense of equidistance between the patient's ego, superego, id, and reality. Rather, it refers to the therapist knowing his or her place and staying out of the patient's personal life (Wachtel 1987, 176–184). Therapeutic neutrality permits the patient's agenda to be given primary consideration. The relative anonymity of the therapist assures that self-disclosures will be kept at a minimum, thus maintaining therapist neutrality. The law also independently recognizes the therapist's duty of neutrality toward patients (Furrow 1980).

The concept of relative neutrality refers to the limitations placed on psychotherapists that prevent interference in the personal lives of their patients. Life choices involving marriage, occupation, where one lives, and with whom one associates, although grist for the therapeutic mill, are basically the patient's final choice (Wachtel 1987, 176–184). Therapists must be very careful about expressing their personal views in the treatment situation concerning, for example, politics, religion, abortion, and divorce.

If an otherwise competent patient is thinking about making a decision that appears foolish or even potentially destructive, the therapist's role is primarily limited to raising the questionable decision as a treatment issue. For example, the therapist can legitimately explore the psychological meaning of the decision as well as its potential adverse consequences for the patient's treatment and life situation. Clinical situations do arise when the psychotherapist must intervene directly. If a patient's decision-making capacity is severely impaired by a mental disorder, the therapist may need to actively intervene to protect the patient or others (Simon 1990b). For example, a psychotically depressed, acutely suicidal patient who refuses to enter a hospital voluntarily requires involuntary hospitalization. Under these circumstances, the clinician intervenes in the patient's life for valid clinical, not personal, reasons.

Patient autonomy and self-determination

Fostering the autonomy and self-determination of the patient is another major principle underlying boundary guidelines. Maintaining patient separateness by supporting the process of separation–individuation follows as a corollary. Of the over 450 current psychotherapies, none holds as a long-term treatment objective that patients remain dependent and psychologically fused with their therapists or others. Obtaining informed consent for proposed procedures and treatments also preserves patient autonomy (Simon 1992). Patient self-determination dictates that the therapist's clinical posture toward the patient should be expectant; that is, the patient primarily determines the content of his or her sessions. This is not the modus operandi, however, in cognitive-behavioral therapies or even with some forms of interpersonal therapy. Moreover, the assurances that physical contact with patients be essentially avoided and that the therapist stay out of the person's personal life (no past, current, or future personal relationships) derive in large measure from the principle of autonomy and self-determination.

Progressive boundary violations invariably constrict the patient's freedom of exploration and choice. Properly maintained treatment boundaries maintain the separateness of the patient from the therapist while also preserving the psychological relatedness of the patient to others.

Fiduciary relationship

As a matter of law, the doctor–patient relationship is fiduciary (*Omer v. Edgren* 1984). The knowledge and power differentials that exist between therapist and patient require the therapist, as a fiduciary, not to exploit the patient for his or her personal advantage. This responsibility is "implicit" in the therapist–patient relationship and is fundamental to the general "duty of care." The special vulnerabilities and dependence of the patient rather than the unique powers of a profession give rise to a fiduciary duty (Simon 1987).

A fiduciary relationship arises, therefore, whenever confidence, faith, and trust are reposed on one side, and domination and influence result on the other (Black 1990). All mental health professionals, not only psychiatrists, have a fiduciary responsibility to their patients. The maintenance of confidentiality, privacy, a stable fee policy, and consistent time and professional treatment settings are based in large measure on the fiduciary duties of the therapist.

Respect for human dignity

Moral, ethical, and professional standards require that psychiatrists treat their patients with compassion and respect. The dedication of physicians to their patients has a long and venerable tradition that finds expression in the Hippocratic Oath. *The Principles of Medical Ethics with Annotations Especially Applicable to Psychiatry* (2013, Section 1) instructs: "A physician shall be dedicated to providing competent medical care, with compassion and respect for human dignity and rights." On clinical grounds alone, the competent therapist always strives to maintain the patient's healthy self-esteem in the course of therapy. Exploitative therapists, however, engage patients as part objects to be used for their own personal gratification. Frequently, such therapists attack the self-esteem of their patients as a means of gaining control over them. All of the boundary guidelines are based on the principle of respect for human dignity.

TREATMENT BOUNDARIES: GENERAL ISSUES

Boundaries in small communities

Psychiatrists and other mental health professionals who practice in small communities and rural areas encounter unique situations and customs that may complicate the task of maintaining treatment boundaries (Simon and Williams 1999). Boundary problems are more likely to occur in maintaining confidentiality and a position of relative therapist neutrality and anonymity. Boundary guidelines must be adaptable to small community practice without endangering the therapeutic frame and the patient.

Exigent boundary settings

In the course of treatment, it may be necessary for the sake of the patient or the welfare of others for the therapist to cross accepted treatment boundaries. The observance of usual treatment boundaries may be interrupted by crises in clinical care, and by intervening, superseding ethical or legal duties. For example, an agoraphobic patient initially may be so incapacitated that he or she is unable to come to the psychiatrist's office. Home visits may be necessary. The potentially violent patient who threatens others creates a conflicting ethical position for the clinician related to the maintenance of confidentiality. The existence of legal requirements to warn and protect endangered third persons may necessitate a breach of the patient's confidentiality. If the patient's cooperation can be enlisted in the process of warning, the treatment boundaries may be maintained. Engaging the patient in the decision to readjust treatment boundaries that result from treatment exigencies may permit salutary boundary reshaping that can facilitate the treatment process. But, according to Gutheil (2005), "theoretically benign boundary crossings can be misconstrued or portrayed in a worse light in later litigation. Boundary crossings thus require circumspection, weighing of pros and cons, and obtaining consultation with a low threshold."

Defensive boundaries

Defensive psychiatry refers to any act or omission that is performed not for the benefit of the patient but to avoid malpractice liability or to provide a legal defense against a malpractice claim. Defensive practices that produce deviant treatment boundaries usually take the form of clinically unnecessary prohibitions that disturb the therapist's position of neutrality. Typical clinical issues that provoke defensive treatment boundaries include *treating* patients with sexual transferences and *managing* potentially violent patients that may require the therapist to warn and protect endangered third parties. Defensive boundaries are usually created by unrecognized or uncorrected therapists' countertransferences (Simon 2000).

Impaired therapists

Impaired therapists usually experience great difficulty in setting and maintaining acceptable treatment boundaries (Olarte 1991). Deviant, aberrant, idiosyncratic boundaries form the basis for patient exploitation. Severely character-disordered therapists tend to repeat boundary deviations with their patients. Predatory, exploitative therapists also belong to this group. Therapists who establish aberrant boundaries may also be incompetent; impaired by alcohol, drugs, and mental illness; situationally distressed by personal crises; or suffering from a paraphilia, particularly frotteurism. Frotteurs have great difficulty in maintaining appropriate physical distance from patients, frequently becoming involved in inappropriate touching.

Psychotherapists with malignant character disorders or paraphilias manifesting severe narcissistic, antisocial, or perverse character traits may simply sexually exploit patients. The mismanagement of transference and countertransference feelings is an epiphenomenon of character impairment.

Vulnerable patients

Every patient is vulnerable to psychological harm from therapists who violate treatment boundaries. Borderline patients are especially at risk for psychic injury (Gutheil 1991). Many of these patients have been physically and sexually abused as children, and their sense of appropriate relationships and boundaries may be seriously impaired.

Treatment boundaries are frequently tested through compulsive repetition of early childhood relationships where personal boundaries were not respected. Highly dependent patients or patients recently experiencing a personal loss are also particularly vulnerable to exploitation.

Although therapists set treatment boundaries, patients invariably test boundaries repeatedly, and in various ways. Healthier patients generally are able to stay within acceptably established treatment boundaries, using the treatment framework productively. More disturbed patients often act out their conflicts around boundary issues. For instance, a patient who was sexually abused as a child may test the integrity of the therapist by continually challenging treatment boundaries. With more disturbed patients, a considerable portion of the therapy may be devoted to examining the psychological meaning of the patient's efforts to gain exceptions to established treatment boundaries. Patients who cannot tolerate limit setting by the therapist may be untreatable (Green et al. 1988).

DISCUSSION OF BOUNDARY GUIDELINES

Neutrality and self-determination

The rule of abstinence and the therapist's position of relative neutrality empower patient separateness, autonomy, and self-determination. Therapists who abandon a position of neutrality and undercut the patient's independence through numerous boundary violations tend to promote a fusional relationship between psychiatrist and patient. In extreme instances, the therapist gradually gains control over the patient's life, making basic life decisions for the patient. Whether done consciously or unconsciously, boundary violations limit a patient's options for independent psychological functioning and recovery. The achievement of psychological independence is a goal of treatment. The maintenance of patient separateness that permits pursuit of this goal is a boundary requirement for the therapist.

Confidentiality

The maintenance of confidentiality is a fundamental boundary guideline that must be adhered to unless specific clinical, ethical, or legal exceptions arise (Simon 1992). Confidentiality must be maintained unless release of information is competently authorized by the patient. Breaches of confidentiality typically occur when therapists find themselves in dual roles (Simon 1987). Such roles usually occur when the therapist must serve simultaneously the patient and a third party. Clinicians working in managed-care settings often find themselves struggling with dual roles (The Hastings Center 1987).

Informed consent

The law requires informed consent for treatments and procedures. Incidental to legal intent, informing patients of the risks and benefits of a proposed treatment maintains patient autonomy and fosters the therapeutic alliance (Simon 1989a). In a number of sexual misconduct cases, drugs and even electroconvulsive therapy have been used to gain control over patients (Simon 1992). *Negligent* medication practices are especially prominent in these cases. Obviously, no effort is made to inform the patient of the risks and benefits of any prescribed medications. Frequently, addictive medications are given, particularly barbiturates and benzodiazepines.

Verbal interaction

The process of psychotherapy requires that the interaction between therapist and patient be essentially verbal. Engaging the patient verbally acts as a check against acting out behaviors by the therapist. In psychotherapy, the therapist must always be alert to the possibility of acting out emotional conflicts with the patient. Acting out may be manifested either by the therapist's behavior or by inducing the patient to act out.

There is, however, a fundamental difference between active interventions utilized by the therapist and therapist acting out. For instance, when somatic therapies or behavioral modification techniques are used, active interventions are made in the service of the treatment, not for the purpose of exploiting the patient (Goisman and Gutheil 1992). Moreover, therapists may find it necessary to actively clinically intervene on behalf of a patient in crisis. All therapies, including Rogersian therapy and even psychoanalysis, employ active interventions and reinforcement approaches (Wachtel 1987, 120–122). The danger to patients and their therapy does not arise from therapist activity *per se*, but rather from therapist acting out.

Bibring (1954) noted that all dynamic psychotherapies variously utilize catharsis, suggestion, manipulation, clarification, and insight in their therapeutic approaches to the patient. Irrespective of the methods favored, the patient should be engaged primarily on a verbal rather than on an action level. Therapists who act out verbally can also seriously harm their patients. However, the behavioral expression of emotional conflict by therapists is usually more damaging to patients.

Personal relationships

Most therapists accept the boundary guideline principle of no previous, current, or future personal relationship with the patient. Past and current personal relationships with patients can hopelessly muddle treatment boundaries and doom any therapeutic efforts. Social chit-chat is not psychotherapy.

Maintaining post-treatment relationships with patients remains controversial (Simon 1992). For a number of sound clinical reasons, post-termination relationships with patients should be avoided (Simon 1992). Transferences can be timeless, raising serious concerns about a former patient's ability for autonomous consent to a post-treatment

relationship. A 1-year waiting period has been proposed that "should minimize problems and allow former patients and therapists to enter into intimate relationships" (Appelbaum and Jorgenson 1991). The vast majority of therapist–patient sexual relationships begin within 6 months of termination. If the therapist thinks about the patient as a future sexual partner, boundary violations likely may result that impair the patient's treatment. *The Principles of Medical Ethics with Annotations Especially Applicable to Psychiatry* (2013, Section 2, annotation 1) states that, "Sexual activity with a current or former patient is unethical."

Physical contact

The avoidance of physical contact with patients is also a controversial issue (Bancroft 1981). Situations may arise in treatment when a handshake or a hug is the appropriate human response. Inoffensive and necessary touching occurs in the course of administering some procedures or treatments. Therapists who work with children, the elderly, and the physically ill frequently find that a caring human touch is comforting and is clinically supportive. An absolute prohibition against touching patients would preclude such therapeutic, human responses.

Nevertheless, therapists must be extremely wary of touching patients. Hugging may seem innocuous, but when carefully scrutinized, may contain erotic messages. Gratuitously touching the patient is clinically inappropriate and may be a prelude to sexual intimacies (Holub and Lee 1990). Holroyd and Brodsky (1989) found that nonerotic hugging, kissing, and touching of opposite-sex patients, but not same-sex patients, was a sex-biased therapy practice associated with a high risk of leading to sexual intercourse with patients. Every patient has the right to maintain the privacy of his or her own body.

Some psychiatrists continue to do their own physical examinations of patients. The transference and countertransference complications of physical examinations performed by the treating psychiatrist are well known. It is important that a physical examination not become the first step to progressive personal involvement with the patient.

Anonymity

Therapist self-disclosure is also a complicated and controversial topic (Stricker and Fisher 1990). Patient and therapist shared regression is one of the obvious dangers of therapist self-disclosure. Some therapists have found the sharing of a past personal experience to be helpful for certain patients in especially supportive psychotherapy. However, the self-disclosure of current conflicts and crises in the therapist's life can induce a role reversal in the patient who then attempts to rescue the therapist. Details of the therapist's personal life, especially fantasies and dreams, should not be shared with patients (Gutheil and Gabbard 1993). Self-disclosures about relationship problems, sexual frustrations, fantasies about the patient, and feelings of loneliness are particularly troublesome for the patient. Therapist self-disclosures not only waste treatment time but also promote a caretaking role on the part of the patient. Therapist self-disclosures, especially about current personal problems and sexual fantasies about the patient, appear to be highly correlated with eventual sexual misconduct (Borys and Pope 1989; Schoener et al. 1989). But, self-disclosure may be necessary if the therapist is suffering from an illness that might negatively affect the treatment or may cause the therapist to be absent from practice for a significant period of time. For example, a therapist's prolonged absence due to illness may require that the patient see another therapist. A simple explanation to the patient would be in order.

The therapist's position of relative anonymity, however, does not require that he or she remain a blank screen. The therapeutic relationship between therapist and patient is essentially interactive (Wachtel 1987, 176–184). For example, the therapist's overt and covert reactions to the patient can be therapeutically valuable in pointing out to the patient the repetitive nature of the patient–therapist interaction as it plays out in other important relationships.

The concept of anonymity and the increased use of social media over the past decade can have many implications for mental health professionals. Information about one's personal and professional life can and is now shared by many people on social media sites such as Facebook, Twitter, LinkedIn, and Instagram. It is important to remember that information posted by a therapist on these sites can be accessed by patients, and vice versa. Mental health professionals should avoid accessing patient information in the social media forum, as there is potential for boundary crossings. Some mental health professionals do utilize social media for business purposes. However, there are risks of engaging in this practice. For example, it has been stated that "While Facebook can be used for professional purposes, the potential dilemmas created by the overlap and interface between friends, family, and professional aspects of your life make it less than ideal as a social media marketing tool for professional purposes such as a psychiatric practice" (Luo 2013a,b). Social media will continue to evolve, and continued caution should be exercised whenever mental health professionals utilize this mode of communication. Koh et al. (2013) propose that "Discipline-specific guidelines for psychiatrists' interactions with social media and electronic communications are needed."

Fees

A fee should be established between the therapist and the patient that is mutually acceptable. Fees may change over time according to economic conditions and the personal circumstances of the patient. Therapists' fees should be paid with money only. The pecuniary value of nonmonetary payments is difficult to establish and should not be accepted (Simon 1992).

Therapists who become sexually involved with patients frequently discontinue billing. Although this practice has a

number of meanings, some therapists do so in the erroneous belief that not billing the patient terminates the treatment relationship and therefore the possibility of being sued. The establishment and continuance of the doctor–patient relationship is not dependent on the payment of a fee (King 1986).

Treatment setting

As Langs (1990) points out, a consistent, relatively neutral treatment setting provides the necessary physical constants that endeavor to maintain "a maximal degree of consistency, certainty, and stability" for the treatment experience to unfold. Because many patients have suffered from inconstancy and intrusiveness in their relationships and physical environments, maintaining a professional treatment setting is psychologically important.

Behavior therapists, however, do accompany phobic patients into threatening environments and situations as part of their legitimate treatment regimen. Therapists with religious orientations may attend a patient's house of worship. Under exceptional circumstances or in an emergency, the therapist may find it necessary to make a house call. Flexibility is necessary because of clinical exigencies and reasonable variations in treatment approaches.

Effective psychotherapy cannot ordinarily be conducted over a telephone. With obvious exceptions, the telephone should be used mainly for making or breaking appointments or for emergencies (Canning et al. 1991). On occasion, therapy may be temporarily conducted over the telephone when the patient cannot come to the office for reasons of work, travel, or physical illness. Medications may require adjustment over the telephone between sessions. Telephone contact may be required in emergencies, but nonemergency telephone interviews should be well-structured, prearranged, time-limited therapeutic engagements that are paid for at the regular rates.

The advent of telemedicine has created a different avenue for patients to obtain mental health treatment without entering a psychiatrist's office. According to the American Telemedicine Association (ATA), telemedicine is formally defined as "the use of medical information exchanged from one site to another via electronic communications to improve a patient's clinical health status. Telemedicine includes a growing variety of applications and services using two-way video, email, smart phones, wireless tools and other forms of telecommunications technology." The ATA offers guidelines regarding the practice of telemedicine. With regard to treatment setting, the ATA recommends, "Both the professional and the patient's room/environment should aim to provide comparable professional specifications of a standard services room." It also suggests, "All efforts shall be taken to use video conferencing applications that have been vetted and have the appropriate verification, confidentiality, and security parameters necessary to be properly utilized for this purpose." (ATA 2013). With the increase in society's use of email communications, psychiatrists should be careful not to become reliant on email to provide complex psychiatric treatment, and again, ensure that security parameters are in place to protect patient confidentiality.

Time

Sessions that are defined in time and length also add stability to the treatment relationship. In sexual misconduct cases, therapy sessions progressively lose time definition, both in scheduling and length. Therapists must always question their reasons for lengthening or shortening sessions. Longer sessions may cause certain patients to feel special and, potentially, more vulnerable to exploitation.

On the other hand, the length of some sessions may require sensitivity to the exigent clinical needs of the patient. Patients in crisis often need additional time during a session. Patients with dissociative *identity* disorders may require flexibility in the length of sessions. Some longer sessions may be needed as various mental states emerge (Putnam 1989).

MONETARY EXPLOITATION

Boundary violations involving money and insurance matters are quite common (Simon 1992). Irregularities concerning patient billing of insurance companies may be only one of a number of boundary violations in the treatment. Any hint of dishonesty in the therapist's dealings with third parties will likely disrupt the therapist's position of neutrality and create mistrust in the therapist–patient relationship. Becoming involved or involving the patient in an acrimonious battle with third-party payers can disrupt boundaries and harm treatment.

Practitioners who become involved in business dealings with patients may later be accused of undue influence when purchasing valuable goods or property from the patient at below-market value, or when the patient leaves the witting therapist a large amount of money in a will (Halleck 1980). The use of "insider information" obtained from the patient for the personal advantage of the therapist occurs with disturbing frequency (American Psychiatric Association 1990). An example of such a practice occurred when a psychiatrist used a stock tip obtained from a bank executive's wife during the course of therapy to turn a large profit (Northrup 1991). Once the Securities and Exchange Commission learned from the patient that "insider" information about a merger was provided, it charged the psychiatrist with profiting illegally. Profits of $26,933.74 were surrendered, and the psychiatrist was fined $150,000 and sentenced to 5 years of probation and 3000 hours of community service (*Washington Post* 1991).

Psychiatrists who work in managed-care settings may face major ethical concerns and potentially serious double-agent roles (Sabin 1989). "Negative incentives" that cut costs at the expense of diminished quality of care represent a significant threat to the therapist's fiduciary commitment to patients (May 1986). Money matters must be secondary to

the clinician's professional, ethical, and legal duty to provide adequate clinical care.

BOUNDARY VIOLATIONS AND MALPRACTICE

In almost all cases of therapist–patient sex, progressive boundary violations precede and accompany the eventual sexual acts (Simon 1989b). Empirical and consultative experience reveals that damaging boundary violations begin insidiously and are progressive. Boundary violations foster malpractice suits by creating a misalliance between therapist and patient. Boundary violations, usually reflecting the personal needs of the therapist, set patient and therapist against one another. Langs observes that the failure to maintain treatment boundaries may lead to autistic, symbiotic, and parasitic relationships with patients (Langs 1990, 339). Langs explains that autistic relationships (severed link) between therapist and patient damage meaningful relatedness, symbiotic (fusional) relationships pathologically gratify the patient, and parasitic (destructive) relationships exploit the patient. Frequently, bad results combined with bad feelings set the stage for a malpractice suit (Gutheil 1989).

Patients usually are psychologically damaged by the precursor boundary violations as well as the sexual exploitation (Schoener 1989; Simon 1991a,b). Even if the therapist and patient stop short of an overt sexual relationship, precursor boundary violations often prevent adequate diagnosis and treatment of the patient. The patient's original mental disorder is often exacerbated and other mental disorders are iatrogenically induced. Thus, therapists may be sued not only for sexual misconduct but also for negligent psychotherapy. Boundary violations that represent deviations in the standard of care and are alleged to have harmed the patient may form the basis of a malpractice suit. In sexual misconduct cases where insurance coverage is excluded, a malpractice claim may be filed based on the numerous, *harmful* boundary violations that precede therapist–patient sex. The following sections in this chapter on civil liability, malpractice cases, and malpractice insurance will further discuss sexual misconduct and malpractice.

DOUBLE AGENTRY

The problem of conflicting loyalties is a major concern to many psychiatrists (Weinstein 1991). Double agentry refers to the psychiatrist's conflicting loyalties when simultaneously serving the patient and an agency, institution, or society (The Hastings Center 1978). In the case of a military psychiatrist, for example, the professional duty owed to the soldier (patient) versus loyalty to the military's best interests poses a potential double-agent role. Prison psychiatrists are frequently confronted with the conflict of having to serve the interests of their prisoner patients, prison officials, and society. School psychiatrists must consider the interests of the student, the parents, and the school administration.

Boundary violations—particularly those involving breaches of confidentiality—may occur when therapists find themselves serving both the patient and a third party. Dual roles often skew the therapist's maintenance of appropriate treatment boundaries. Therapists must inform patients from the very beginning about any limitations placed on the patient's treatment, and particularly limits on confidentiality because of dual responsibilities of the therapist.

Practitioners may hold personal agendas that create a conflict of interest, disturbing the therapist's position of neutrality and creating legal liability. For example, in *Roe v. Doe* (1977) a psychiatrist was sued by a former patient for publishing a book that reported verbatim information from the therapy, including the patient's thoughts, feelings, and fantasies.

SEXUAL MISCONDUCT

Standard of care

The Principles of Medical Ethics with Annotations Especially Applicable to Psychiatry unequivocally prohibits sex with a current or former patient (2013). This ethical position has a venerable tradition in medicine since the time of Hippocrates. Sex between the therapist and the patient is negligence *per se* (Simon 1992). Therapist–patient sex is a violation of those statutes that govern the licensing and regulation of mental health professionals, incorporating ethical codes adopted by the professions that specifically prohibit sexual contact between therapist and patient. It is also unequivocal evidence of professional incompetence. The psychiatrist holds himself or herself out to the public as having standard professional skill and knowledge. The psychiatrist "must have and use the knowledge, skill, and care ordinarily possessed and employed by members of the profession in good standing" (Keeton et al. 1984). Because a respected minority of psychiatrists does not exist who will state that sex with a patient falls within the standard skill and knowledge of psychiatrists, sex between psychiatrist and patient is an unquestioned and unchallenged deviation in the standard of care.

An increasing number of states are limiting by statute the period of time after treatment ends whereby psychotherapists may be held legally liable for sexual involvement with a former patient (Gartrell et al. 1986). Some state statutes provide immunity from legal liability for sex between therapist and a former patient that occurs after a prescribed period of time, usually 1–2 years following termination (Bisbing et al., 1995, 755–756). Appelbaum and Jorgenson (1991) have proposed a 1-year waiting period that "should minimize problems and allow former patients and therapists to enter into intimate relationships." Because approximately 98% of sexual contact with former patients occurs within a year of initial clinical contact, most statutory time limits prohibiting post-treatment sex more than adequately cover the time of maximal vulnerability of patients to sexual exploitation (Gartrell et al. 1986). But, if the therapist entertains the prospect of sex with the patient in the

future, boundary violations likely may result that impair the patient's treatment.

Nevertheless, although it may not be illegal for psychotherapists to have sex with a former patient after expiration of a statutorily prohibited period, it is unethical for psychiatrists to do so. The patient may not have had a therapeutic termination but rather an interrupted therapy by the therapist who anticipates having sex with the patient. Post-treatment sex with the patient often signals the presence of earlier precursor boundary violations by the therapist. Frequently, therapists who entertain the possibility of post-treatment sex with a patient communicate this desire during the course of treatment.

Therapist sex with a former patient presents complex ethical and legal issues. Some therapists marry their former patients. Moreover, constitutional issues surrounding the right of association and the competence of the former patient to choose freely complicate the legal analysis of post-treatment sex (Schoener et al. 1989). Clinically, however, the matter is much simpler. The most credible policy is to avoid sex with former patients. A closed-door policy toward former patients should be considered. Once the patient enters the door of the psychotherapist's office, it is forever closed to the possibility of a sexual relationship. Aside from ethical and legal concerns, a number of sound clinical reasons exist for this position (Simon 1992).

Sexual relations between supervisor and trainee also raise ethical issues. *The Principles of Medical Ethics with Annotations Especially Applicable to Psychiatry* states the following:

> Sexual involvement between a faculty member or supervisor and a trainee or student, in those situations in which an abuse of power can occur, often takes advantage of inequalities in the working relationship and may be unethical because: (a) any treatment of a patient being supervised may be deleteriously affected; (b) it may damage the trust relationship between teacher and student; and (c) teachers are important professional role models for their trainees and affect their trainees' future professional behavior. (Section 4, annotation 14, 2013)

Therapist–patient sex: Clinical issues, boundary violations

The road to therapist–patient sex is littered with numerous boundary violations (Simon 1999). Sexual misconduct rarely happens suddenly, but rather is usually preceded by progressive, increasingly damaging precursor boundary violations (Simon 1989b). The precursor boundary violations usually psychologically harm the patient by interfering with appropriate diagnosis and treatment (Simon 1991a). Precursor boundary violations can cause serious psychological injury, even if the therapist and patient stop short of a sexual relationship.

Although every case of sexual misconduct is unique, a "typical" scenario can be derived from cases evaluated for litigation:

- Therapist's position of neutrality is gradually eroded in "little" ways.
- Therapist and patient address each other by first name.
- Therapy sessions become less clinical and more social.
- Therapist's self-disclosures occur, usually about current problems and sexual fantasies about the patient.
- Therapist begins touching patient, usually by hugs and embraces.
- Therapist gains control over patient, usually by manipulating the transference and by medications.
- Therapy sessions become extended in time.
- Therapy sessions are rescheduled at the end of the day.
- Therapist and patient have drinks/dinner after sessions; dating begins.
- Therapist–patient sex begins.

Because precursor boundary violations to therapist–patient sex usually occur gradually and incrementally, the therapist may have time to restore treatment boundaries. Empirical and consultative experience reveals that damaging boundary violations begin insidiously and are progressive. During the segment of the therapy session that occurs "between the chair and the door," patients and therapists are more vulnerable to committing boundary excursions and violations. Inchoate boundary violations with a potential for damaging progression usually first appear within this interval. This part of the session can be scrutinized for early warning of boundary violations and studied for its instructive value in risk management and prevention of sexual misconduct (Gutheil and Simon 1995).

Epstein and Simon (1990) have devised an Exploitation Index that can be used by therapists as an early warning indicator of treatment boundary violations. A survey of 532 psychiatrists using the Exploitation Index revealed that 43% found that one or more questions alerted them to boundary violations, while 29% were stimulated to make specific changes in treatment practices (Epstein et al. 1992).

TRANSFERENCE EXPLOITATION

Patients who come for psychiatric treatment are undergoing painful mental and emotional suffering that is often debilitating. As a consequence, their decision-making capacity and judgment usually are impaired. Moreover, the therapist is viewed as a critically important source of help and hope. Under these circumstances, a patient's transference of expectant beneficence may develop that is highly influenced by early, powerful wishes for nurture and care. The therapist is frequently idealized as the all-good, all-giving parent. Combined with the fear of losing the newly acquired idealized parental figure, the beneficent transference leaves the patient vulnerable to exploitation by the therapist. The beneficent transference is a common psychological reaction, experienced to varying degrees by practically all patients.

It should be distinguished from the transference neurosis that develops in a number of patients usually undergoing intensive, psychodynamic psychotherapy.

Unlike the physician who works intuitively within the gambit of a positive transference that provides hope and succor to the patient, psychiatrists and other mental health professionals frequently work directly with transference phenomena as a therapeutic tool. As a treatment strategy in intensive psychotherapy or psychoanalysis, the therapist may encourage development of the transference but then is expected to keep countertransference feelings in check for the benefit of the patient. Biologically or behaviorally trained psychiatrists and psychotherapists may not place much emphasis on transference issues in treatment. Nevertheless, the importance of transference is well known and must be recognized by all therapists, regardless of their training and theoretical background. The legal concepts of undue influence and breach of fiduciary trust may be utilized in place of the concept of transference in the civil litigation of sexual misconduct cases involving biologically or behaviorally trained therapists (Simon 1991b).

The issue of patient transference and the competence to consent to therapist–patient sex sometimes arises in the context of litigation (Simon 1994). However, the breach of fiduciary trust by the therapist who engages in sex with the patient should be the appropriate focus of wrongdoing (Simon 1992). Thus, "In sexual misconduct cases, the issue is never the patient's consent but always breach of fiduciary trust by the therapist" (Simon 2003).

Certain patients appear to be particularly vulnerable to sexual exploitation. Patients with borderline, dependent, and histrionic personality disorders are vulnerable to sexual exploitation because significant potential exists for developing intense erotic and dependent transferences. The borderline patient may attempt to live out her or his transference with the therapist. Exceptions to treatment boundaries may be sought constantly (Gutheil 1989).

Many patients who are victims of sexual misconduct have been physically and sexually abused as children. In therapy, formerly abused patients tend to constantly test treatment boundaries to assess the integrity of the therapist. Exploitative therapists take advantage of these patients' efforts to find a person in authority whom they can begin to trust. No matter how seductive the patient, the therapist is expected to maintain his or her treatment neutrality while attempting to understand the meaning of the seductive behavior with the patient. The therapist charged with sexual misconduct by the patient cannot complain that he or she was seduced.

Civil liability

Malpractice is the most common form of legal liability in sexual misconduct cases. Litigation is almost always sparked by a real or perceived rejection of the patient by the therapist that shatters the patient's sense of specialness. If it is just the plaintiff's word against the therapist's word that therapist–patient sex took place, proving the case against the therapist may be very difficult. In these cases, the forensic psychiatrist's position on either side of the litigation should be one of neutrality concerning the factual dispute. A tenable stance is that if the therapist did engage in a sexual relationship with the patient, then negligence did occur.

When it can be demonstrated that significant boundary violations have occurred, the plaintiff's case alleging sexual misconduct by the therapist is bolstered. Although the presence of typical precursor boundary violations makes it more likely that sexual misconduct occurred, it cannot be inferred with certainty that an actual therapist–patient sexual relationship took place. If the plaintiff can provide corroborating evidence to support the allegations of sexual misconduct, such as testimony from other abused (former) patients, letters, pictures, hotel or motel receipts, and identifying body marks, then the legal defense of the therapist becomes very difficult.

The psychiatrist evaluating psychological damages will be asked to distinguish the pre-injury from post-injury psychiatric status of the abused patient. Pope and Bouhoutsos (1986, 45–56) have described a "therapist–patient sex syndrome." This syndrome may not be distinct, but probably reflects the existence of comorbidity so often seen in victims of therapists' sexual misconduct. A study by Bouhoutsos et al. (1983) found that 90% of the patients were damaged by therapist–patient sexual intimacies. Pope and Bouhoutsos, in their review of the literature, state, "overall, the balance of the empirical findings is heavily weighed in the direction of serious harm resulting to almost all patients sexually involved with their therapists" (Pope and Bouhoutsos 1986, 63). Guidelines for the assessment of psychological harm caused by therapist-patient sex have been proposed (Pope 1989; Schoener et al. 1989, 133–145). A systematic approach to the evaluation of claims of therapist–patient sexual misconduct also requires considerations of false accusations in order to maintain a balanced forensic perspective (Gutheil 1992).

Malpractice cases

A few representative malpractice cases will illustrate the general position that courts have taken in undue familiarity litigation. For example, the injurious nature of precursor boundary violations was underscored in *Zipkin v. Freeman* (1968), one of the earliest sexual misconduct cases. The defendant psychiatrist was found to have manipulated the patient to his advantage by convincing the patient to become his mistress and to leave her husband. The patient alleged that she had sex with the psychiatrist and attended "group therapy" that involved nude swimming. She complained that the psychiatrist mishandled the transference, which a psychiatrist is expected to handle properly. The judge stated:

> Once Dr. Freeman started to mishandle the transference phenomena, with which he was plainly charged in the petition and which is overwhelmingly shown in the evidence, it was

> inevitable that trouble was ahead. It is pretty clear from the medical evidence that the damage would have been done to Mrs. Zipkin even if the trips outside the state were carefully chaperoned, the swimming done with suits on, and if there had been ballroom dancing instead of sexual relations.

The jury awarded the patient monetary damages of $17,000.

Before the *Roy v. Hartogs* decision in 1976, there was little significant litigation arising from sexual involvement between psychiatrists and patients. In *Hartogs*, for the first time, large monetary damages were awarded after Dr. Hartogs attempted to treat his patient's fear of being a lesbian by initiating a sexual relationship with her. The court held that the psychotherapist–patient relationship was a fiduciary relationship similar to a guardian–ward relationship. The court further stated, "there is a public policy to protect a patient from the deliberate and malicious abuse of power and breach of trust by a psychiatrist when the patient entrusts to him her body and mind."

In *Simmons v. United States* (1986), the court addressed the consequences of mishandling the transference:

> The impacts of sexual involvement with one's counselor are more severe than the impacts of merely "having an affair" for two major reasons: First, because the client's attraction is based on transference, the sexual contact is ordinarily akin to engaging in sexual activity with a parent, and carries with it the feelings of shame, guilt, and anxiety experienced by incest victims. Second, the client is usually suffering from all or some of the psychological problems that brought him or her into therapy to begin with. As a result, the client is especially vulnerable to the added stress created by the feelings of shame, guilt, and anxiety produced by the incestuous nature of the relationship, and by the sense of betrayal that is felt when the client eventually learns that she is not "special" as she had been led to believe, and that her trust has been violated.

Malpractice insurance

Most professional liability insurers will not insure for sexual misconduct, excluding it as an intentional tort or criminal action. The rationale for this is that because sexual misconduct is not practice, it cannot be malpractice. Some malpractice policies will cover the costs of litigation but not the cost of damages. Other insurers will only cover the therapist if the charge of sexual misconduct is denied.

The negligent management of transference and countertransference has been alleged as a cause of therapist sexual misconduct and is covered by some professional liability policies. Because this allegation may be self-serving on the part of the therapist, the testimony of an expert witness may be necessary in a legal action between the therapist and the carrier.

As previously stated, most cases of therapist–patient sex are preceded by progressive treatment boundary violations. As a result, patients are usually psychologically damaged by precursor boundary violations in addition to the eventual sexual misconduct of the therapist (Simon 1991a). The therapist's mismanagement of boundaries may fall under the negligence provisions of his or her professional liability policy. The trend of court decisions in undue familiarity litigation favors compensation of victims.

The statute of limitations may be invoked in sexual misconduct cases. For example, in *Decker v. Fink* (1980), a sexual misconduct case, the Maryland Special Court of Appeals ruled that the plaintiff's impaired judgment, presumably because of the effects of transference, was not "sufficient legal justification for failing to timely file [a] medical malpractice action, and evidence established that [the] plaintiff knew or should have known [of the] existence of her alleged cause of action." In *Riley v. Presnell* (1991), however, the Massachusetts Supreme Judicial Court invoked the discovery rule, which tolled (stopped) the statute of limitations from running. It rejected the defendant's defense that it was too late to bring a malpractice suit 7 years after the alleged sexual misconduct. The plaintiff successfully contended that he was unable to discover the psychological injuries resulting from the sexual misconduct because of the harm caused by the psychiatrist's behavior. In cases that involve exploitation of the patient, the therapist's negligence may impair the patient's ability to become aware of the psychological injuries that are produced (Jorgenson and Appelbaum 1991). In *Colburn v. Kopit* (2002), the Colorado Court of Appeals found that, according to Colorado law, "An action for negligence or outrageous conduct must be filed within two years after the cause of action accrues." The finding of the appellate court was that "the statute of limitations for plaintiff's claims of breach of fiduciary duty, negligence, and outrageous conduct had expired before plaintiff filed this action."

Idealization of the therapist may prevent the patient from discovering his or her injury, thus permitting the presence of transference to toll the statute of limitations. Fraudulent concealment of negligence by the therapist also may toll the statute; for example, it may occur in therapist–patient sex when the therapist informs the patient that sex is therapy, or when the therapist does not inform the patient that he or she is under the influence of transference.

Civil and criminal statutes

An increasing number of states have statutorily made sexual activity both civilly and criminally actionable. For instance, Minnesota has enacted legislation that states:

> A cause of action against a psychotherapist for sexual exploitation exists for a patient or former patient for injury caused by sexual contact with the psychotherapist if the sexual contact

> occurred: (1) during the period the patient was receiving psychotherapy…or (2) after the period the patient received psychotherapy…if (a) the former patient was emotionally dependent on the psychotherapist; or (b) the sexual contact occurred by means of therapeutic deception. (Minn. Stat. Ann. §604.201, 2014)

Some states make therapist–patient sex *negligence per se* by statute, creating a nonrebuttable presumption concerning the therapist's duty of care (Simon 1992). To establish liability, the plaintiff need only prove that sexual contact occurred and caused damage.

In legislation prohibiting therapist–patient sexual exploitation, sexual behavior is defined in a variety of ways, some so vague as to invite constitutional challenges based on violation of the Due Process Clause in state constitutions and the U.S. Constitution (Jorgenson et al. 1991). Most statutes define sexual activity as intercourse, rape, the touching of breasts and genitals, cunnilingus, fellatio, sodomy, and inappropriate or unnecessary examinations and procedures performed for sexual gratification. Obviously, statutory definitions cannot possibly encompass the wide variety of sexual activities that constitute abuse of patients by a therapist.

Three basic types of remedies have been codified into reporting, civil liability, and criminal statutes (Appelbaum 1991; Strasburger et al. 1991). Reporting statutes require the disclosure to state authorities by a therapist who learns of any past or current therapist–patient sex. A few states have civil statutes proscribing sexual misconduct. The civil statutes incorporate a standard of care and make malpractice suits easier to pursue. For example, Minnesota has enacted a statute that provides a specific cause of action against psychiatrists and other psychotherapists for injury caused by sexual contact with a patient (Simon 1992). Some of these statutes also restrict unfettered discovery of the plaintiff's past sexual history. Criminal sanctions may be the only remedy for exploitative therapists without malpractice insurance, who are unlicensed, or who do not belong to professional organizations.

Sexual exploitation of a patient, under certain circumstances, may be considered rape or some analogous sexual offense and therefore criminally actionable. Typically, the criminality of the exploitation is determined by one of three factors: the practitioner's means of inducement, the age of the victim, or the availability of a relevant state criminal code.

Some states can, and do, prosecute sexual exploitation suits using their sexual assault statutes (Simon 1992). Sex with a current patient may be criminally actionable if the state can prove beyond a reasonable doubt that the patient was coerced into engaging in the sexual act. Typically, this type of coercion is limited to the use of some form of substance, such as medication, to either induce compliance or reduce resistance. Anesthesia, electroconvulsive treatment, hypnosis, force, and threat of harm all have been used to coerce patients into sexual submission (Schoener et al. 1989, 331). To date, claims of "psychological coercion" via the manipulation of transference phenomena have not been successful in establishing the coercion necessary for a criminal case. In cases involving a minor patient, the issue of consent or coercion is irrelevant, because minors and incompetents (including adult incompetents) are unable to provide valid consent. Therefore, sex with a child or an incompetent is automatically considered a criminal act.

Wisconsin and an increasing number of other states make sexual relations between a therapist and patient a statutory criminal offense (Bisbing et al. 1995). For example, the Wisconsin statute holds:

> Any person who is or who holds himself or herself out to be a therapist and who intentionally has sexual contact with a patient or client during any ongoing therapist–patient or therapist–client relationship regardless of whether it occurs during any treatment, consultation, interview, or examination is guilty of a class F felony. Consent is not an issue in an action under this subsection. (Wis. Stat. Ann. §940.22[2], 2014)

Professional disciplinary action

In addition to civil and criminal liability, psychiatrists who engage in sex with patients also can become embroiled in ethics proceedings conducted by professional organizations. The statute of limitations does not apply in ethics proceedings. Moreover, for the purpose of adjudicating allegations of professional misconduct, licensing boards typically are granted certain regulatory and disciplinary authority by state statutes. As a result, state licensing organizations, unlike professional associations, may discipline an offending professional more effectively and punitively by suspending or revoking his or her license. Because licensing boards are not as restrained by the rigorous rules of evidence that exist in civil and criminal actions, it generally is less difficult for the patient to seek redress through this means. Published reports of sexual misconduct adjudicated before licensing boards generally reveal that if the evidence was reasonably sufficient to substantiate a claim of exploitation, the professional's license was revoked or the professional was suspended from practice for varying lengths of time, including permanent suspension. The Federation of State Medical Boards has published a report titled *Addressing Sexual Boundaries: Guidelines for State Medical Boards* that "provides recommendations to assist medical boards with the investigation process, preparation for formal hearings, crafting an appropriate disciplinary response, physician monitoring, and physician education" in cases of alleged physician sexual misconduct.

Reporting sexual misconduct

Reporting the alleged sexual misconduct of other therapists based on the statements of patients is fraught with complex

clinical, ethical, and professional issues. Requiring mandatory reporting may create serious double-agent roles for the therapist that can undermine subsequent treatment interventions with the exploited patient. A few states require reporting of sexual misconduct by therapists (Bisbing et al., 1995, 168–169). In most states with reporting requirements involving therapist–patient sex, reporting may not proceed without the patient's consent.

Clinical flexibility regarding reporting is required in the treatment and management of sexually exploited patients. When the patient is a therapist who reports exploiting his or her patient, does a *Tarasoff* duty to warn and protect his or her other patients arise? Conflicting ethical issues exist surrounding breaching confidentiality versus potential *Tarasoff* duties arising from the discovery of a patient–therapist's continuing sexual exploitation (Eth and Leong 1990).

The requirement to report an impaired colleague or the allegation of sexual misconduct often conflicts with the duty to maintain patient confidentiality. Some abused patients do not want their sexual relationship with a therapist made public. If the patient is the offending therapist, the conflict between reporting and maintaining confidentiality is further heightened because reporting likely would doom the therapy and unilaterally expose the patient (therapist) to grave personal and professional consequences.

Second, the reports of therapist sexual misconduct by a patient may not be true. False allegations of therapist–patient sex are a relatively rare phenomenon. Nevertheless, the new therapist should withhold judgment upon hearing charges of sexual misconduct against another therapist. Furthermore, the patient should decide about bringing allegations of therapist sexual misconduct in the open, except where mandatory reporting by the therapist is required. Thus, the question of reporting is turned into a treatment issue.

Third, treatment may be the most pressing need for the patient who has been sexually abused. Unfortunately, the patient may have to choose between treatment and litigation. Psychotherapy and litigation do not mix. The emotional turmoil and the additional stress the patient may experience when involved in litigation are often too disruptive to the continuing conduct of psychotherapy. Nevertheless, some therapists believe that therapeutic value exists for the plaintiff in pursuing a suit in overcoming helplessness, expressing anger and revenge, and resolving trauma.

Fourth, a therapist's zeal to report another therapist's alleged sexual abuse without regard to the patient's clinical status can further psychologically damage the patient. Abused patients have been re-victimized by therapists who have attempted to undo the trauma caused by the initial sexual exploitation. A common scenario occurs when the therapist bends over backward to try to prove his or her own trustworthiness to the patient or to try to re-parent the patient. As a consequence, serious, damaging boundary violations have occurred (Simon 2001). The maintenance of therapist neutrality is critical in these cases and should not be construed as a conspiracy of professional silence.

The new therapist faced with a patient alleging sexual exploitation should consider consultation with a forensic psychiatrist familiar with the legal and ethical issues surrounding allegations of sexual misconduct. The therapist may be better able to maintain a treatment role while the forensic consultant handles the legal issues with the patient. The therapist's provision of detailed psychiatric testimony gleaned in the course of therapy may utterly destroy the treatment relationship and sorely vex the therapist (Strasburger 1987).

Prevention

The sexual exploitation of patients is not correlated with the level of training or the theoretical persuasion of the therapist. Gartrell et al. (1986) found offenders were more likely to have graduated from an accredited residency and to have undergone personal psychotherapy or psychoanalysis. Thus, all therapists must be educated about sexual misconduct and the devastating consequences for the patient and the therapist. In tutorials and seminars, therapists need to be taught that the principle of abstinence requires that the therapist's primary source of gratification arise from the treatment process with the patient. The therapist's position of neutrality demands that the patient not be exploited as a personal source of gratification for the therapist. Receiving a fee for professional services is the only material satisfaction provided directly by the patient.

Moreover, therapists must be sensitized to the boundary violation precursors to therapist–patient sex. Because precursor boundary violations occur over time, the alerted therapist may be able to restore treatment boundaries before the patient is harmed or progression to therapist–patient sex occurs (Simon 1995). Of course, therapists with severe character disorders who relate to patients through manipulation and exploitation cannot be expected to benefit very much from educational efforts.

Therapists who find themselves sexually attracted to patients and in danger of acting out their feelings must consider the following:

- Consultation with a colleague
- Referral of the patient (with no further contact)
- Personal therapy
- Acknowledging personal and professional limitations with certain patients
- All of the above

Feelings of sexual attraction by therapists toward patients are common. A survey of 575 psychotherapists found that 87% felt sexually attracted to their clients, but only 9.4% of men and 2.5% of women acted out such feelings (Pope et al. 1986). Unfortunately, countertransference feelings, particularly the erotic variety, have become associated with mismanagement of the patient's treatment and are viewed with shame and embarrassment by some therapists. Countertransference, however, when properly managed,

can be used as an important therapeutic tool (Heimann 1950). Alternatively, ignorance of countertransference phenomena may harm the therapeutic process.

SUMMARY

Treatment boundaries fluctuate in response to the dynamic, psychological interaction between therapist and patient. As a consequence, boundary crossings and violations occur in almost every therapy. The boundary-sensitive therapist usually can reestablish treatment boundaries before the patient is psychologically harmed. Although "minor" boundary excursions initially may appear innocuous, they can represent inchoate violations along the progression to eventual exploitation of the patient.

A spot test can be applied by the boundary-sensitive therapist to determine whether he or she has committed a boundary violation: first, is the intervention in question done for the benefit of the therapist or for the sake of the patient's therapy? Second, is the intervention in question part of a series of progressive boundary violations? If the answer to either is "yes," the therapist is on notice to desist immediately and to take corrective action. If basic treatment boundaries are violated and the patient is harmed, therapists may be sued, may be charged with ethical violations, and may lose their professional license.

Malpractice suits against psychotherapists alleging undue familiarity continue. Unlike the aftermath of other malpractice actions, the consequences for the offending therapist go far beyond large monetary judgments. The professional and personal disgrace, ethical proceedings, criminal proceedings, loss of licensure, as well as the loss of income, friends, and family are just some of the disastrous consequences that can occur. Numerous efforts to address this serious problem continue through civil and criminal litigation, legislation of protective statutes, and education of laypeople and professionals alike.

SUMMARY KEY POINTS

- Boundary guidelines for psychotherapy, such as maintaining therapist neutrality and separateness, confidentiality, informed consent, no personal relationship with the patient, minimization of physical contact, preservation of therapist anonymity, fee and session length stability, and a professional setting can help maintain the integrity of the treatment process.
- *The Principles of Medical Ethics with Annotations Especially Applicable to Psychiatry* unequivocally prohibit sex with a current or former patient (2013). Therapist–patient sex is a violation of those statutes that govern the licensing and regulation of mental health professionals, incorporating ethical codes adopted by the professions that specifically prohibit sexual contact between therapist and patient. It is also unequivocal evidence of professional incompetence.
- It may not be illegal for psychotherapists to have sex with a former patient after expiration of a statutorily prohibited period of time, but it is unethical for psychiatrists to do so. Malpractice is the most common form of legal liability in sexual misconduct cases. Most professional liability insurers will not insure for sexual misconduct, excluding it as an intentional tort or criminal action.
- An increasing number of states have statutorily made sexual activity both civilly and criminally actionable. In addition to civil and criminal liability, state licensing organizations, unlike professional associations, may discipline an offending professional by suspending or revoking his or her license.

The law and the physician: Ill physicians

MICHAEL GENDEL AND PAUL D. COOPER

INTRODUCTION

This chapter will review how physicians suffering from mental illness, including substance use disorders and other illnesses, are affected by regulatory law, policies of hospitals and other workplaces, and reporting and certifying agencies. It also will discuss problems and protections in other areas of civil law that are posed by physician illness. Special issues in defending, assessing, treating, and monitoring ill physicians will be explored. The significant role of state physician health programs in modulating the workings of regulatory law and administrative policy, as they affect sick doctors, also will be discussed.

CONVERGING LEGAL AND HEALTH ISSUES

The development of legal mechanisms to address ill physicians: Limitations

That illness potentially could impair a doctor at work, and thus endanger patients, has been recognized in published literature since the nineteenth century. However, there was little published in the scientific literature about physician health matters until the last 40 years. The handling of ill physicians generally has been the purview of state licensing boards, under the concept of "regulation of physician practice." These boards were established and began functioning in the United States in the latter half of the nineteenth century. The laws, and the licensing boards that they created, were meant to protect the public by defining "professional" and "unprofessional" behavior. Beginning in the nineteenth century (and, in some jurisdictions, continuing to the present day), being addicted to drugs and/or alcohol (usually referred to as "habitual intemperance") was considered unprofessional behavior rather than illness. Under this legal doctrine, a doctor could/can be disciplined simply for being ill (i.e., addicted to drugs and/or alcohol), rather than while actually practicing in an impaired condition or unsafe manner (Walzer 1990).

When state medical boards take action against physicians, a "sanction-oriented" approach has significant practical consequences, which limit this approach's effectiveness. For example, when otherwise qualified and capable doctors lose their ability to practice, their patients experience significant consequences and the already-strained physician workforce is further depleted. As Dilts and Sargent wrote in an earlier edition of this textbook, "Simply weeding out detected offenders did not materially advance the safety of patients, was needlessly wasteful of valuable medical skills and, not least, was inhumane" (Dilts and Sargent 2003, 171). Improved regulatory practices have permitted doctors, whose practices are adversely affected by the symptoms and disability caused by illness, to enter into formal arrangements with their state's medical board to obtain appropriate treatment, while continuing to practice under specified conditions and limitations, rather than be sanctioned (e.g., be formally admonished, have their medical license suspended or revoked). These arrangements are called probationary agreements, stipulations, or consent agreements.

The difficulty for the legal system in addressing ill physicians is that neither discipline nor peer review is likely to affect or improve problematic, unskilled, or unprofessional behavior caused by illness. One of the basic tenets of Anglo-American legal systems is that those subject to the system will act with rational self-interest and therefore are likely to respond to actual or threatened sanctions. However, this tenet applies imperfectly to those with serious illness (either mental or physical) or substance use disorders. For example, in the case of substance use disorders, sufferers are notoriously resistant to entering treatment or remaining sober even when facing significant adverse consequences. In fact, according to the *Diagnostic and Statistical Manual of Mental Disorders*, 5th edition (*DSM-V*), five of the diagnostic criteria for a substance use disorder involve continuing to use the substance despite adverse consequences (American Psychiatric Association 2013, 4483–4484). Similar difficulties also are associated with many psychiatric disorders, because judgment, motivation, behavioral control, social functioning, and cognition are often affected.

Many medical disorders also impact these functions, either directly (in neurological disorders) or indirectly (in many or most serious medical illnesses in which downstream emotional consequences are significant). Therefore, if illness is a cause of problematic physician performance or behavior, treatment for the underlying condition is the most effective remedy, and the one most likely to provide protection to the public. Medical board-imposed or peer review-imposed sanctions are less likely to be effective.

Illness, impairment, fitness, and incompetence

"Impaired physician" was a term used to describe ill physicians in early regulatory law, public policy dialogue, and the scientific literature. This nomenclature continued until very recently. Indeed, only in 2013 did the Federation of State Medical Boards (FSMB) publish guidelines for the return to work of physicians who had been out because of illness (Federation of State Medical Boards 2013); in previous FSMB literature ill physicians were termed "impaired." As of 2014, based on the presumption of impairment, many member boards of the American Board of Medical Specialties (ABMS) will not allow physicians to retain their board certification or sit for board examinations if they are currently subject to a medical board action. This is true even if this action is related solely to their being ill, rather than their having exhibited any unprofessional conduct or impairment in the work setting. There is a fundamental distinction between the concepts of illness and impairment. An "ill physician" is one who suffers from any illness or injury. An "impaired physician" is one whose illness has so adversely affected their ability to practice medicine that they cannot do so safely. An evaluation of the relationship between a physician's illness/injury and the physician's ability to practice safely is called a "fitness-for-duty evaluation." Guidelines for conducting such an evaluation are published by the American Psychiatric Association and addressed in scientific journals (Anfang et al. 2005) and in this chapter.

Until the mid-1980s, the phrase "impaired physician" was synonymous with physicians who suffered only from substance use disorders (SUDs). It did not include other medical and psychiatric illnesses that potentially could cause impairment, and was used to describe doctors with SUDs even if they were never impaired at work. In part, this was because treatment centers that specialized in treating health professionals with substance use disorders had been established in the United States, and doctors recovering from substance use disorders were active in helping their similarly afflicted colleagues. This practice was in contrast to professional silence about other important physician health problems. In 1973, this silence was broken dramatically with the publication of "The Sick Physician" in the *Journal of the American Medical Association* (American Medical Association 1973). This article defined an impaired physician as one unable to "practice medicine with reasonable skill and safety to patients by reason of mental or physical illness, including but not limited to deterioration through the aging process, or loss of motor skills, or excessive use or abuse of drugs, including alcohol." This publication also suggested that doctors developed certain illnesses (e.g., heart disease and cancer) at higher rates than the general population, and were more likely to commit suicide. Although completed suicide is more common among physicians, particularly female doctors, than the general population (Center et al. 2003), most other illnesses appear to affect doctors at rates similar to the general population of the United States. This notwithstanding, the aim of "The Sick Physician" was to underscore the need for doctors' health to be addressed and to identify potential obstacles to doing so (e.g., personal obstacles [denial, fear of licensure problems] and professional obstacles [lack of knowledge about and skill in helping sick doctors, the "conspiracy of silence"]).

"Incompetence" is a term for physicians whose knowledge or skills are insufficient to practice safely. "Illness" refers to doctors suffering from a medical or psychiatric illness (including substance use disorders). "Impairment" is a term for doctors whose illness (or injury) leads to the inability to practice safely because the symptoms of their illness cause such substantial disability at work. There is not necessarily any relationship between incompetence, illness, and impairment. A doctor with competence problems is not usually ill, though both competent and incompetent doctors may become ill. Illness may affect competent functioning if it is severe or lengthy enough to interfere with ongoing learning (e.g., difficulty learning due to cognitive impairment by neurologic disease), impacts decision making (e.g., impulsive decision making associated with mania), or affects the exercise of the doctor's skills (e.g., tremor that affects a surgeon's performance). If this impact is substantial enough to render a doctor unsafe to practice medicine, then the doctor is impaired. "Impaired" is a better term than "incompetent" for describing such a physician because it speaks to causes and remedies that are distinct from the educational approach used in addressing a "primary" deficit in knowledge and/or skill. The assessment of competence and its remediation is a matter separate from the assessment of fitness and is generally performed by different individuals or organizations than those who assess fitness for duty (Grace et al. 2014).

The evolution and central role of physician health programs (PHPs)

In the 1970s, a movement to help ill physicians began to take shape. It was motivated largely by the medical profession's response to the publication of "The Sick Physician." "Impaired Physician Committees" were formed, usually under the aegis of a state medical society. These committees were staffed by volunteer physicians. These individuals assisted other physicians who came forward for help voluntarily and intervened involuntarily in fairly obvious cases of impairment. Generally, the committee's efforts were unstructured, and the committee had no specific relationship with that jurisdiction's medical licensing board. Most

volunteers were physicians in recovery from substance use disorder(s), and their focus was, somewhat understandably, on substance use disorders. Most of those attempting to provide assistance had no formal training in treating substance use disorders, other than what they had gleaned from their own experience with that illness.

Over time, it became clear that informal committees were not sufficient to handle the number of ill doctors, the complexity of medical and psychiatric problems from which doctor's suffer, and the equally complex effects of illness on their professional and personal lives. The need to help these doctors was sufficiently compelling that the volunteer committees became programs, which subsequently developed increased structure, more comprehensive policies and procedures, and better defined, though widely varying relationships with licensing boards, medical societies, malpractice insurance carriers, hospitals, and practice groups (DuPont et al. 2009). Leaders in the field of physician health learned that not only did doctors need to be able to access care for a variety of health problems, but also that those who evaluated and treated ill doctors had acquired expertise in working with their special problems; this argued for the "professionalization" of PHPs (rather than relying on a volunteer workforce). Challenges of working with ill physicians include that they have a very educated form of "denial of illness" (Stoudemire and Rhoads 1983, 654; Gendel 2005, 49); problems asking for help even when they know they are ill; the belief that they can best diagnose and treat themselves; complex patterns of self-prescribing and self-treatment (Gendel et al. 2011); profound fears of loss of confidentiality (Schneck 1998); and a host of issues pertaining to their workplace, career path, and family.

In 1986, Colorado established the first physician health program that was designed to assist physicians in addressing every potential health problem they might face (Caspar et al. 1988), as well as a variety of personal and social problems. The program operated under the assumption that the earlier a health, personal, or social problem was addressed with an appropriate intervention, the less likely it was to cause serious personal and professional sequelae (including impairment). Therefore, the program targeted problems such as work stress, malpractice stress, distress about bad patient outcomes, and marital and family problems. The program also attended to problems with professional boundaries and other workplace behavior problems (Dilts et al. 1994; Gendel 2000). With time, programs in other states began to address a similar scope of issues, and currently, most programs in the United States and Canada address at least some health and behavior problems in addition to substance use disorders. However, the "problem areas" served by these programs still vary greatly from state to state. The same variability exists with regard to funding source, staffing, and confidentiality policies. Current information about each state program may be found at the website of the Federation of State Physician Health Programs (FSPHP) (http://www.fsphp.org/sites/default/files/pdfs/2005_fsphp_guidelines-master.pdf), a national organization of U.S. PHPs. This organization facilitates the work of state PHPs, conducts an annual national meeting, promotes physician health research, and develops and updates guidelines for PHP work.

Almost all PHPs are authorized by their state's licensing board to monitor the ill physician's health problems. This involves evaluating his or her clinical condition over time, adherence to recommended treatment interventions, and participation in tissue testing for addictive substances (if indicated). This relationship is defined by state law and/or medical board policy and by the structure of the PHP. In some states, physician participants are not known to the board unless the physician is determined by the PHP to be a risk to patients, is noncompliant with PHP recommendations, or had been referred initially to the PHP by the medical board. In some states, every physician participant is known to the board. In other states, some but not all medical board members know the identity of each participant. Similarly, PHPs may be an entity separate from the board and other medical institutions, may operate directly under the auspices of the board, or may be related to a medical society or a malpractice carrier. In all states, PHPs monitor ill physicians when directed to do so by their state's medical board. In order to understand the legal ramifications of a physician's participating in a PHP, those working with ill doctors must know the relationship between the PHP and the medical board in their state.

There is a growing body of research related to the outcomes of physician health programs. Recent studies of physicians with substance use disorders demonstrate extremely high success rates compared to other populations (McLellan et al. 2008). A universal definition of "success" has not been determined, however. Relapse rates may be less important than rates of sustained periods of work. In fact, physician relapse rates are poor predictors of long-term outcomes (Brooks et al. 2012a). The scientific literature related to PHPs and physicians with mental illness is less robust but tends to suggest similar success rates (Knight et al. 2007). Studies of outcomes related to PHPs and physicians with "physical illness" are more difficult to interpret because of the conditions' heterogeneity. A small body of research has shown PHPs to be effective in improving outcomes for physicians with "boundary" problems (Brooks et al. 2012b).

More recently, research has focused on the effectiveness of PHPs in improving patient safety by using malpractice claims as a proxy measure for dangerous physician behavior. One study by Brooks et al. (2013) examined whether physicians' involvement in a PHP reduced the number of "claims paid" by their malpractice carriers. The study found that claims were paid less often on behalf of physicians after a PHP intervention (compared to a control group with no history of problem behavior or PHP intervention). It also found that although PHP-involved physicians had been at higher risk of increased "claims paid" than a control group before PHP participation, their risk post-PHP intervention was statistically significantly lower than the controls.

Presently, there are several issues that are problematic in the field of physician health. Stress and the stress syndrome,

"burnout," appear to be serious and almost ubiquitous problems among physicians, and recent evidence links symptoms of burnout to medical errors (Shanafelt et al. 2010). In helping physicians prevent and manage stress, PHPs eventually must include in the process the institutions in which physicians work. Although most physicians are naturally hard-working and somewhat compulsive (Gabbard 1985), unabated stress and overwork can lead to significant personal and professional difficulties. Suicide rates among doctors, particularly female doctors (who complete suicide at a much higher rate than females in the general population), remain a significant problem despite a growing awareness of and concern about this phenomenon (Center et al. 2003). Most doctors with suicidal ideation do not seek mental health treatment (Shanafelt et al. 2011), probably at least partially because of the stigma of mental illness and the fear of negative professional consequences. In order to address this problem, PHPs, as well as other involved organizations and institutions, must help change "the culture of medicine" so that physicians can more readily seek out and receive potentially life-saving assistance. Additionally, physicians, medical institutions, and licensing boards should collaboratively develop sensible guidelines for addressing age-related cognitive decline among physicians, though cognitive problems do not exist solely in older doctors (Gendel et al. 2014). If such guidelines, informed by physician health research, are not developed, doctors could be subject to public policy and evaluation strategies that are reactive and ill-considered.

REGULATORY LAW AND THE ILL PHYSICIAN

The state licensing board's power

Control of the ill physician's ability to legally practice has generally been established via state law and is augmented by hospital regulations and medical ethics. Although statutes vary from state to state, most justify modifying (or terminating) a physician's unrestricted ability to practice whenever "impairment" is found; that is, the physician suffers from an illness that creates a strong likelihood of misconduct that, in turn, endangers patients. In most states, the medical board may investigate a physician if there is "a reasonable suspicion" of the existence of a potentially impairing illness.

State authority to regulate medical practice comes from its "police power," a residual constitutional power (Article 11) conferred upon the state by the Tenth Amendment. This authority was designed to help the state preserve and promote the health, safety, and welfare of its citizens. In most states, this authority is codified in a medical practice act (MPA) that empowers the licensing board to determine the fitness of licensees, both at entry into practice and on an ongoing basis. Regulatory action can be initiated because of complaints to the board or by the board itself "for cause." The medical board's authority over the ill physician is a specific example of this general power.

Board procedures

After the medical board receives a complaint against a physician, it notifies the physician of the complaint and provides the physician an opportunity to address (and refute) the allegation, either in writing or at an informal meeting. The initial complaint is a critical stage of the regulatory process of physician practice. Many liability insurance carriers have recognized the benefit, and perhaps necessity, of providing legal counsel (at the carrier's expense) to its insured physicians at this early stage of the proceedings. By doing so, malpractice carriers have realized significant ultimate savings, often avoiding having to defend their insureds from subsequent malpractice complaints.

When a licensing board perceives or suspects that physician illness may be a contributor to or cause of the alleged misconduct, it may refer the matter to a PHP, which then evaluates the physician. Medical practice acts routinely require physicians to limit their practice to areas in which their illness will not compromise their ability to practice safely.

If a physician is alleged to be in violation of that state's MPA, the medical board's ultimate findings can include dismissal, nondisciplinary letters to the physician/licensee indicating that the matter is being dismissed despite the board's having certain concerns, letters of admonition, stipulations to limit practice (either by consent or board proceedings), full probationary stipulations, license suspension, and license revocation. Records of such sanctions are maintained by the board to guide its consideration of any future complaints. If the complaint is found to be without merit, it may be dismissed. If a complaint does not result in a finding of a violation of the MPA but gives the board information about the physician's practice that may be of concern about possible future practice issues, the board may issue a letter of concern (LOC). Such a letter is maintained for a short period of time (usually 6 months) in case the concerning conduct recurs. A dismissal or LOC need not be reported on future license applications. The other sanctions are required to be reported, and a failure to do so is a violation of the MPA.

The domino effect

Complaints to the medical board are often either the catalyst for or component of the cascade of events known as the "domino effect."

Physician conduct is subject to review by a myriad of agencies and entities. These include federal and state law enforcement authorities, state medical boards, the American Medical Association (AMA), local medical societies, hospitals (via granting or restricting of hospital privileges), the American Board of Medical Specialties (via board certification), insurance provider panels, practice groups (including HMOs), insurance malpractice carriers (via determinations of coverage), the civil courts (via malpractice litigation), and, in high-profile cases, the media. A complaint to any

of these entities may lead to other reviewing authorities' initiating an investigation. This "domino effect" sometimes creates additional, significant problems for the practitioner, particularly when the physician is suffering from an illness that compromises his or her ability to cope with typical stressors of life, much less to deal with multiple, potentially public inquiries into the their conduct. Confusion on the part of any of the reviewing authorities related to the difference between illness, impairment, and incompetence can trigger this effect.

For instance, if a physician is found to be ill and in need of monitoring, the state medical board may enter into a license stipulation by which the physician must agree to be treated and monitored for a defined period of time. This stipulation is considered a license "restriction." This license restriction subsequently is reported by the state medical board to the Federation of State Medical Boards (FSMB). The FSMB then relays this information to the American Board of Medical Specialties (ABMS). The ABMS's member specialty boards generally do not permit a physician under a practice restriction by a medical board to maintain board certification (or to sit for the certification examination). In turn, this loss of board certification may jeopardize the physician's hospital privileges or membership on health insurance provider panels. In order to minimize the potential unfairness of this cascade effect, both the ABMS and the FSMB, in conjunction with the FSPHP, are developing a process by which each "restriction" would be reviewed carefully. This review would attempt to distinguish which stipulations reflected unprofessional conduct (and would continue to affect board certification) and which were based only on the physician's being ill. Such a process, carefully implemented and undertaken, presumably would minimize ill physicians' exposure to multiple, professionally crippling consequences.

In an effort to provide the public with information about impaired physicians, Congress enacted legislation establishing the National Practitioners Data Bank (NPDB), which gathers and makes available to select entities information about physicians' medical board sanctions, civil malpractice suit settlements, and criminal convictions, among other information. Unfortunately, the accessing entity often does not recognize the difference between illness, impairment, and incompetence. Also, once definitive sanctions are imposed, the physician's otherwise confidential health information may be available on the NPDB. Ultimately, physicians may be placed in the problematic position of having to choose between the confidentiality of their health information and the risk of having sanctions imposed and publicized because of conduct related to illness. By defending an allegation via attributing its etiology to an underlying illness, physicians risk losing their right to privacy regarding their diagnosis and medical care.

Physician health programs have proved effective in reducing the "domino effect" by decreasing the pressure on hospitals' (and other entities') peer review and privileging processes. Previously, these groups were required to determine whether or not an ill physician's practice was so affected by illness that a complaint should be made to the medical board, despite their not necessarily having the training or experience to make such a determination. If referred by reviewing authorities, PHPs are able to conduct or orchestrate the evaluation, and if need be, treatment of physicians without their being reported to the medical board. In cases in which a report must be made to the medical board (the legal criteria for which vary from state to state), the PHP can provide more nuanced information to the board regarding the nature and extent of illness and the relative roles of illness and impairment in causing the conduct under consideration; this can lead to less punitive board action. PHP-led evaluations also reduce the exposure of reviewing authorities (e.g., hospitals) to litigation over the correctness of their evaluations.

The "safe harbor" provision of some medical practice acts (Colorado Medical Practice Act 2014) is an extremely important safeguard against the "domino effect." Under this provision, physicians applying or re-applying for licensure may legally answer "no" to the health questions, provided their case is "known" to the PHP. "Known" means that the physician has been evaluated by a PHP and is currently in compliance with the PHP's recommendations. The benefit of such provisions to the physician and the public is the prevention of the domino effect during the period in which the physician and his treatment providers address the medical condition, without the distractions of defending their professional reputation against multiple investigations or reviews.

CIVIL LAW AND THE ILL PHYSICIAN

Malpractice

In virtually every state, tort laws provide remedies to patients who suffer damages because of negligent physician conduct. The legal theory underlying these laws is commonly referred to as medical malpractice. Ill physicians, particularly those with mental illness or cognitive impairments, may have difficulty understanding the proceedings against them, cooperating with their counsel, testifying in a coherent manner about their treatment and the reasons for it, and maintaining their energy level during these often arduous legal proceedings. Attorneys pursuing malpractice claims frequently attempt to introduce the physician's/defendant's confidential health information in an attempt to buttress the claim against the physician. Generally, courts have denied access to such information, noting that it is irrelevant to those proceedings. If the physician were ill but not negligent, it would be unfair to allow the evidence to be admitted, given the high risk of such evidence prejudicing the jury against the physician (*Watson v. Chapman*, 343 S.C. 471, 2000; *Griffin v. McKenney*, 2002-CA-00353-COA, 2003). Such prejudice could lead to verdicts or settlements favorable to the plaintiff, even if there had been no malpractice.

Americans with Disabilities Act

The Americans with Disabilities Act (ADA), which was enacted in 1990, also can impact an ill physician's practice and recovery. The ADA requires that a "disabled person" receive "reasonable accommodations" in order to permit them to perform the essential duties of their employment/job. In the past, physical disabilities, mental health conditions, cognitive impairment, and substance use disorders have been accommodated, and the physicians affected by them have proved able to practice safely. Regular shifts for emergency doctors suffering from bipolar disorder, reduced workloads for conditions that slow the physician's performance, and careful monitoring of physicians with substance use disorders are all accommodations that have been effective and allowed physicians to continue to provide valuable medical services. Courts have defined reasonable accommodation on a case-by-case basis, weighing the difficulty of applying the remedy against the benefit of the services provided. If the accommodation is expensive or lengthy, the courts may not enforce the requirement. If the necessary accommodation is minimal, such as allowing physicians to dictate medical records rather than requiring them to enter the data by hand, it is very likely to be granted.

Confidentiality

During the course of litigation, licensing proceedings, or other matters, an ill physician is frequently asked to disclose his or her own health information. A physician should only produce these otherwise confidential records after careful consideration and discussion with legal counsel. A physician's involvement in civil litigation (particularly as a defendant) or licensing proceedings themselves does not vitiate his or her right to withhold confidential health information. In such cases, this information is generally not sufficiently relevant to the issues litigated to justify its release. Even if the information is required to be disclosed, its use should be restricted to that particular proceeding.

PHPs provide an extremely important filter for an ill physician's personal health information and help protect the confidentiality of this information. With the physician's consent, the PHP can provide only relevant and necessary information to reviewing authorities; reviewers need not directly view health records. However, with the PHP's involvement, the reviewers can be confident that they have a clear picture of the physician's functioning, treatment, and prognosis. This mechanism has preserved an important degree of confidentiality for the doctor. Written reports of PHPs need not and should not be made public.

Corporate practice of medicine

The case of *Darling v. Charleston Hospital* (1965) 211 N.E.2d 253 (Ill.) has led to many claims against hospitals, essentially for providing the domain in which an ill or impaired physician may practice. Because doctors are not normally employees of hospitals but rather independent practitioners exercising their own clinical judgment in treating patients, courts have traditionally refused to hold hospitals liable for actions of hospital staff physicians. The *Darling* case raised the possibility of liabilities being imposed on hospitals as a result of a physician's misconduct. In cases in which the hospital has knowledge of a physician's misconduct but fails to take appropriate action, or misleads the public about the physician's relationship to the hospital, the hospital may be held responsible for physician conduct. As hospitals purchase more physician practices and employ more physicians on a full-time basis, they risk increased liability for their physician-employees' malpractice.

SPECIAL ISSUES FOR THE ILL PHYSICIAN

Legal defense of the ill physician

For an attorney, defending a competent and healthy physician (e.g., in a malpractice suit) is often challenging, even if the facts of the case support the physician's care. Defending an ill physician presents additional challenges. As an initial step, the physician's attorney must become educated about his or her client's health condition and its potential ramifications on the physician's delivery of medical care. In order to accomplish this goal, the attorney likely will need to communicate with the physician's health-care providers, PHP, or both, and the physician will need consent to this. This information should help the attorney ascertain the degree to which he and she can rely on the physician-client's assistance in the case, and the physician's ability to testify effectively. It also will help the attorney to determine whether and how the stress of extended litigation (e.g., malpractice) will negatively impact the physician's well-being. The physician will need education and reassurance about the legal process in order to withstand its rigors, and should actively engage the defense attorney regarding questions, concerns, and fears. Family issues often prevent full communication of these issues with spouses or partners. The physician is usually too embarrassed to discuss the case with colleagues. The physician's reliance on his or her attorney is often the difference between success and failure in legal proceedings; however, the attorney also relies on the physician for education about the medical facts and issues that will be crucial to a successful defense of the doctor. The attorney may make requests for medical articles pertinent to the case and may benefit from witnessing a procedure, being shown and educated about the use of medical instruments that were involved, and learning the complication rates for the procedure at other institutions or in other practices. The physician and attorney, and the case, will benefit from shared professional knowledge and experience.

In many cases, it is helpful for counsel to educate his or her client about the legal system and process, in order to minimize unrealistic fears. It also may be productive for the attorney to assign the physician tasks, the completion of which will assist in the physician's defense. This helps the

physician gain some sense of control in the case and feel that he or she is actually defending himself or herself. In many cases, the attorney will be the doctor's most important social support. It is also important for the attorney to determine whether or not the physician's illness adversely impacted patient care, and if so, to proceed to defend the case with that in mind. Before the physician's deposition, the attorney must attempt to discern whether opposing counsel will try to inject the physician's illness into the legal proceedings. If so, the attorney should research legal authorities related to the relevance and admissibility of such information, and decide whether a waiver of confidentiality is needed in order to argue lack of relevance.

The role of forensic psychiatrists and fitness-for-duty evaluations

Forensic psychiatrists, either as PHP employees or independent consultants, often are asked to evaluate ill physicians and to relay their findings to and collaborate with a variety of the institutions and organizations previously discussed. Many of these assessments are "fitness-for-duty" evaluations, which in this context are designed to assess the severity of a physician's illness or injury and such illness's or injury's impact on the physician's ability to safely perform the duties of his or her job (Gendel 2006, 668). In such an examination, it is essential to note the presence or absence of an illness or injury, evidence supporting the diagnosis, the symptoms reported by the evaluee, the signs noted by the evaluator, and the effect of the signs and symptoms on the physician's functioning in specific domains. The forensic psychiatrist eventually will opine as to which, if any, workplace functions are impacted and whether, overall, the doctor is or is not impaired and can or cannot practice medicine safely. The forensic psychiatrist also may be asked to opine about potential treatment interventions, prognosis, specific functional domains that require remediation/restoration, and means for monitoring and assessing the treatment's efficacy in improving the physician's functioning. In addition to fitness-for-duty evaluations, forensic psychiatrists may be asked to evaluate other issues that require forensic expertise, such as disability insurance claims, or whether a doctor's condition may be appropriate for accommodations under the ADA.

Treating the ill physician

Confidentiality, though always an important consideration in psychiatric or medical treatment, is especially crucial in the psychiatric treatment of ill physicians. At the outset of treatment, the treating physician should explain to his or her patient that communication with spouses, family members, co-workers, PHPs, licensing boards, hospitals, and employers is often necessary in order to complete a comprehensive, accurate assessment and initiate appropriate treatment. The treating physician should clearly explain when and why communication with these sources may be necessary and obtain written consent from the patient. As at the beginning of any mental health treatment relationship, the treating physician should explain which situations would lead to a "breach" in confidentiality (e.g., suicidality, child abuse reporting, elder abuse reporting, credible threats against an identifiable victim).

In some states, the MPA may mandate that a treating physician report the physician to the medical licensing board if the treater has a reasonable suspicion that the physician/patient is impaired or has displayed unprofessional conduct that violates the law. For example, in Colorado (Colorado Medical Practices Act 2014), a nontreating physician is required to report another physician to the medical board if he or she has knowledge or belief that the physician has violated the MPA in any way. Treating physicians are not required to report their physician-patients to the medical board unless they have knowledge or belief that the physician-patient cannot practice safely.

Many treating psychiatrists and other physicians are inexperienced or untrained in providing treatment to doctors. Two common mistakes are made (Dilts and Gendel 2000, 126). In some cases, there is a tendency to "over-identify" with the doctor-patient, assume the doctor-patient knows more about his or her condition than he or she does, to consider the doctor-patient unlikely to be seriously ill, and to be hesitant to subject the doctor-patient to the rigors of a time-consuming or painful workup; this leads to undertreatment. In other cases, conversely, treating physicians may feel challenged and practice defensively, not demonstrating the flexibility required to help doctors feel sufficiently special (by virtue of their profession) to tolerate the patient role, and thus depriving them of the ability to be a partner in their care; this often leads to the physician-patient's leaving treatment. Additionally, many clinically oriented psychiatrists are reluctant to advise their physician-patients to suspend their practice, even if they are very ill and likely impaired, because they are understandably focused on their supportive role and may be inexperienced in and timid about confronting their patients' level of disability. Recommending that the physician-patient take time off also has implications for the patient's self-esteem and identity as a capable doctor, not to mention financial ramifications. Consultation with a forensic psychiatrist or other physician skilled in making these decisions is always useful.

Physician-patients often feel ashamed of being ill, and may think that their knowledge of medicine, psychiatry, or substance use disorders should have been protective against developing such problems. Keeping this possibility in mind helps improve empathy in the treating physician. To the extent that such patients are "under fire," or believe that they are, from the licensing board, hospital, employer, litigant-patient, or from themselves (because of a bad patient outcome), the injury to self-esteem can be profound. Such doctors require much support and are at high risk for completed suicide. Including the patient's spouse, family, friends, and colleagues in the treatment plan can be very important.

Monitoring the ill physician

PHPs do the bulk of the monitoring of ill physicians, either as a result of referral from the licensing board or other entity, or as a result of the physician voluntarily seeking assessment, treatment referral, and monitoring. As noted previously, the FSPHP has published guidelines for the monitoring of physicians with substance use disorders and some other mental health conditions (FSPHP 2005). "Monitoring" refers to a type of follow-up over time, during which a PHP (or occasionally a psychiatrist or physician in the community) that is not a treatment provider for the doctor but functions in an otherwise clinical role, provides periodic assessment of the course of a physician's treatment, clinical status, and, frequently, workplace functioning. This process involves meeting with the physician and gathering collateral information from those treating the physician and, potentially, the physician's spouse, family members, employer, supervisor, colleagues, and/or co-workers. Physicians with substance use disorders usually are asked to attend and complete their primary treatment in a residential or outpatient setting, and subsequently are asked to attend aftercare, remain abstinent, utilize 12-step programs, follow recommendations of treatment providers, and participate in tissue screening and other monitoring activities (e.g., face-to-face meetings). Tissues sampled may include urine, blood, hair, nails, breath, saliva, or sweat. Each tissue type has advantages and disadvantages for monitoring purposes (Verebey et al. 2005). The frequency, length, and means of monitoring vary by PHP. For other psychiatric and medical disorders, the monitoring process is similar, absent the requirements for abstinence and, typically, tissue screening. However, ongoing laboratory monitoring may be required, (e.g., lithium level). PHPs attempt to keep private as many details as possible of the participant-doctor's health information and treatment. Even if information needs to be disclosed to a licensing board or other entity, a PHP can distill the relevant material and keep confidential irrelevant, specific information. Because treatment providers are much less experienced in providing such information, they tend to reveal more information than is necessary to regulatory bodies and other reviewing agencies (e.g., hospital credentialing committees).

SUMMARY

Ill physicians may be subject to various laws and policies, particularly regulatory law. This regulatory law generally is interpreted and enforced by a medical licensing board, which may sanction the physician for behavior that it considers unprofessional. Sanctions are unlikely to remedy problematic behavior caused by illness; typically, only treatment and monitoring can maintain or restore the ill doctor's ability to practice safely. Physician health programs provide an environment in which an ill physician may receive assessment, treatment referral, and monitoring, either in coordination with a licensing entity or, in most cases, confidentially. Attorneys representing ill physicians should be aware of the special needs of these clients. Additionally, psychiatrists and other treaters should be aware of these patients' special treatment needs.

SUMMARY KEY POINTS

- Illness, impairment, and incompetence among physicians are separate concerns, though aspects of each overlap with one another.
- Forensic evaluation of fitness-for-duty addresses the relationship between illness and potential work impairment.
- Medical board sanctions will not necessarily remedy unprofessional behavior caused by mental illness, substance use disorders, or other medical conditions.
- Assessment, treatment, and monitoring can be instrumental in maintaining or restoring a doctor's ability to practice medicine safely.
- An ill physician may face unique legal questions and unusual confidentiality concerns.
- The ill physician requires legal representation and medical care by individuals skilled in the defense or treatment of ill physicians.

The law and physician prescribing of controlled substances

GREGORY SOKOLOV

INTRODUCTION

A forensic psychiatrist may be asked to evaluate a physician who is accused of illegally or negligently prescribing controlled substances in a variety of different contexts. These may include (a) criminal prosecution, in which the physician was illegally prescribing controlled substances for distribution or personal use; (b) civil litigation proceedings (e.g., malpractice suit), where the prescribing physician fell below a reasonable standard of care in prescribing controlled substances, leading to damages for or death of a patient(s); or (c) state medical board investigations/proceedings regarding a physician's prescribing of controlled substances and/or possible impairment because of abuse of controlled substances.

PRESCRIPTION OPIOID ABUSE

The use of "prescription painkillers," referring to opioid or "narcotic" pain relievers, including drugs such as hydrocodone, oxycodone, and hydromorphone, has steadily increased in the United States over the past 10 years. Healthcare providers wrote 259 million prescriptions for painkillers in 2012, enough for every American adult to have one. An increase in drug overdose deaths is associated with this rise in number of prescriptions. According to the Centers for Disease Control and Prevention (CDC), in 2012, there were 41,502 deaths due to drug poisoning (often referred to as drug-overdose deaths) in the United States, of which 16,007 involved opioid analgesics and 5925 involved heroin. A recent study showed that contemporary heroin users were older men and women living in less urban areas, who were introduced to opioids through prescription medications (Cicero et al. 2014).

In addition to drug overdose deaths and a rise in illicit opioid addiction rates, prescription opioids also have been associated with an increased rate of criminal behaviors (e.g., theft, illegal sales, and other forms of "drug diversion"). Drug diversion is defined as the intentional transfer of a controlled substance from an authorized to an unauthorized possessor (Cicero et al. 2011). Data from a set of selected states show that prescription controlled substances were diverted by theft almost 13,000 times from 2000 to 2003. In 2003 alone, two million doses of six opioid analgesics were reported stolen from the supply chain, mainly retail pharmacies (Joranson and Gilson 2005).

As a result of rampant prescription opioid abuse and related criminal activity, the Drug Enforcement Administration (DEA) increased its enforcement efforts to prevent abuse and diversion of OxyContin (oxycodone). This marked the first time the agency had targeted a specific brand-name product for monitoring. In 2006, the DEA reported that 71 physicians had been arrested for crimes related to "diversion," the leakage of prescription medication into illegal drug markets. In addition, in 2014, hydrocodone-containing products were re-scheduled by the DEA from Schedule III to Schedule II, allowing for stricter monitoring of prescriptions.

BACKGROUND LAWS

In 1970, the 91st U.S. Congress passed the Drug Abuse and Prevention Control Act, which was signed into law by President Richard M. Nixon. Title II of the Act is entitled "The Controlled Substances Act," which allows licensed medical professionals to prescribe, dispense, and administer controlled substances for legitimate medical purposes in the course of professional practice.

The Controlled Substances Act established schedules for controlled substances ranging from Schedule I (most restrictive) to Schedule V (least restrictive). Drugs on Schedule I have no currently accepted medical use in the United States and a high potential for abuse. Schedule I drugs are listed as the "most dangerous drugs of all the drug schedules," with potentially severe psychological or physical dependence; Schedule I drugs include heroin and marijuana. Schedule II drugs are defined as drugs with a high potential for abuse,

though less abuse potential than Schedule I drugs. These drugs are also considered dangerous, and include the opioid pain medications oxycodone and hydromorphone, as well as psychostimulants. Schedule III drugs include buprenorphine and codeine-containing products. Schedule IV drugs include benzodiazepines and barbiturates, in addition to sedative–hypnotic agents (zolpidem, zaleplon).

The "control" portion of the Controlled Substances Act attempts to prevent diversion, establishes a system of secure manufacture and distribution, requires record-keeping procedures, and sets up penalties (including criminal prosecution) for violating its provisions. Civil and criminal sanctions for serious violations of the statute are part of the government's control apparatus. The Code of Federal Regulations (Title 21, Chapter 2) implements the Controlled Substances Act.

In the 1975 ruling *United States v. Moore*, the U.S. Supreme Court confirmed that physicians who are licensed by the Drug Enforcement Agency to prescribe narcotics under the Controlled Substances Act "can be prosecuted when their activities fall outside the usual course of professional practice."

It is imperative that physicians be thoroughly familiar not only with federal laws regarding the prescription of controlled substances but also with their own state's laws and regulatory practice standards. Access to these laws, or summaries thereof, is available through the Federation of State Medical Boards (FSMB).

PRESCRIPTION DRUG MONITORING PROGRAMS

In response to the problems of diversion and abuse of prescription medications, the federal government and many states have created prescription drug monitoring programs (PDMPs). Typically, PDMPs collect prescribing and dispensing data from pharmacies, conduct reviews and analyses of the data, and disseminate the relevant data to appropriate regulatory and law enforcement agencies.

Following the lead of New York in the 1910s, California and Hawaii enacted PDMPs in the 1940s. By the 1980s, seven more states had added PDMPs. As of November 2014, all states (with the exception of Missouri and the District of Columbia) have enacted legislation creating PDMPs. However, only 40 states currently have operational PDMPs. The National Alliance for Model State Drug Laws (http://www.namsdl.org) provides links to each state's statutes and regulations regarding PDMPs.

Certain characteristics of PDMPs can have a deterrent effect on potential criminal activities associated with controlled substance prescriptions. For example, some state authorities report that use of tamper-resistant prescription forms significantly reduces or eliminates prescription forgery. In addition, PDMPs that make prescribing information available to health-care professionals at the point of clinical care may be useful for identifying "doctor shopping." An individual who is immediately identified with such a history should have the treatment plan re-evaluated, and a referral for substance abuse treatment should be considered.

In California, the state's database, known as the Controlled Substance Utilization Review and Evaluation System (CURES), contains over 100 million entries of controlled substance medications that have been dispensed in California. Each year, the CURES program responds to more than 60,000 requests for information from practitioners and pharmacists.

In New York, effective August 27, 2013, most prescribers are required to consult the Prescription Monitoring Program (PMP) Registry when writing prescriptions for Schedule II, III, and IV controlled substances. The PMP Registry is also available to New York-licensed pharmacists. One of the unique aspects of New York law is the requirement that prescribers consult the PMP Registry when writing prescriptions for commonly prescribed psychiatric medications, including benzodiazepines and psychostimulants. In addition, prescribers in New York are required to have an individual Health Commerce System account to gain access to the PMP, and can designate others, including unlicensed office and ward staff, residents, and interns, as individuals who can check the database for the physician prior to the physician's prescribing. Penalties for prescribers who do not review the PMP prior to prescribing include escalating fines for first, second, and subsequent violations.

Research has demonstrated significant benefits of PDMPs for practitioners. A study of emergency medicine clinicians conducted in Ohio in 2010 found that prescribing practices changed in 41% of encounters when PDMP data were provided to the physician prior to his or her prescribing. Study authors also reported that in some cases, access to PDMP data resulted in increased, rather than decreased, prescribing, indicating that access to PDMP information potentially could facilitate more individualized controlled substance prescribing (Baehren et al. 2010). In another review paper, Gugelmann et al. (2012) concluded that although more research on the immediate and downstream effects of PDMPs is needed, these databases show significant promise in stemming the tide of prescription opioid diversion, abuse, dependence, and overdose. If states heed current recommendations regarding design, implementation, maintenance, security protections, and user education, PDMPs could prove to be an essential component in curtailing the current epidemic of prescription opioid abuse (Gugelmann et al. 2012).

Model policy

The FSMB assists state medical boards in protecting the public and improving the quality and integrity of health care in the United States. In April 1998, the Federation adopted the *Model Guidelines for the Use of Controlled Substances for the Treatment of Pain*, which was widely distributed to state medical boards, medical professional organizations, other health-care regulatory boards, patient advocacy groups, pharmaceutical companies, state and federal regulatory agencies, and practicing physicians and

other health-care providers. The *Model Guidelines* have been endorsed by the American Academy of Pain Medicine, the Drug Enforcement Administration, the American Pain Society, and the National Association of State Controlled Substances Authorities. In April 2003, the *Model Guidelines* were updated and revised to become *Model Policy*. The goal of the revision was to provide state medical boards with an updated template about the appropriate management of pain that was in compliance with applicable state and federal laws and regulations (FSMB 2004).

The *Model Policy* has adopted the following criteria, which should be used when evaluating whether a physician's treatment of a patient's pain with controlled substances was appropriate

1. *Evaluation of the patient*: A medical history and physical examination must be obtained, evaluated, and documented in the medical record. The medical record should document the nature and intensity of the pain, current and past treatments for pain, underlying or coexisting diseases or conditions, the effect of the pain on physical and psychological function, and history of substance abuse. The medical record also should document the presence of one or more recognized medical indications for the use of a controlled substance.
2. *Treatment plan*: The written treatment plan should state objectives that will be used to determine treatment success, such as pain relief and improved physical and psychosocial function, and should indicate if any further diagnostic evaluations or other treatments are planned. After treatment begins, the physician should adjust drug therapy to the individual medical needs of the patient.
3. *Informed consent and agreement for treatment*: The physician should discuss the risks and benefits of the use of controlled substances with the patient, persons designated by the patient, or with the patient's surrogate or guardian if the patient does not have medical decision-making capacity. The patient should receive prescriptions from one physician and one pharmacy whenever possible. If the patient is at high risk for medication abuse or has a history of substance abuse, the physician should consider the use of a written agreement between the physician and patient outlining the patient's responsibilities, including (a) submitting to urine/serum medication levels screening when requested; (b) knowing the number and frequency of all prescription refills; and (c) understanding the reasons for which drug therapy may be discontinued.
4. *Periodic review*: The physician should periodically review the course of pain treatment and consider any new information about the etiology of the patient's pain or the patient's state of health. Continuation or modification of controlled substances regimens for pain management depends on the physician's evaluation of progress toward treatment objectives. If the patient's progress is unsatisfactory, the physician should assess the appropriateness of continued use of the current treatment plan and consider the use of other therapeutic modalities.
5. *Consultation*: The physician should be willing to refer the patient as necessary for additional evaluation and treatment in order to achieve treatment objectives. Special attention should be given to those patients who are at increased risk for medication misuse, abuse, or diversion. The management of pain in patients with a history of substance abuse or with a comorbid psychiatric disorder may require extra care, monitoring, documentation, and consultation with, or referral, to an expert in the management of such patients.
6. *Medical records*: The physician should keep accurate and complete records including, but not necessarily limited to (a) medical history and physical examination; (b) diagnostic, therapeutic, and laboratory results; (c) evaluations and consultations; (d) treatment objectives; (e) discussion of risks and benefits; (f) informed consent; (g) treatments; (h) medications, including type, dosage, quantity, and date prescribed; (i) instructions and agreements; and (j) periodic reviews.
7. *Compliance with controlled substances laws and regulations*: To prescribe, dispense, or administer controlled substances, the physician must be licensed in the state in which the medications are prescribed and comply with applicable federal and state regulations.

RISK EVALUATION AND MITIGATION STRATEGIES (REMS)

The Food and Drug Administration (FDA) Amendments Act of 2007 gave the FDA the authority to require a Risk Evaluation and Mitigation Strategy (REMS) from manufacturers to ensure that the benefits of a drug or biological product outweigh its risks. A REMS can include a medication guide, a patient package insert, a communication plan, elements to assure safe use, and an implementation system. The first opioid to be subject to the new REMS requirement was the recently approved fentanyl buccal soluble film. The FDA plans to extend mandatory REMS to other opioids, including all rapid-onset formulations and, eventually, all long-acting opioids, whether or not they are already FDA approved. In one published survey, 50% of the responding physicians were willing to comply with the mandatory education component of the REMS, including the requirement to provide education to patients, in order to continue to be able to prescribe the medication. However, a significant minority of physicians seemed unwilling to prescribe opioids subject to the new REMS requirement. Therefore, REMS could have the unintended effect of decreasing access to opioid medications for legitimate medical purposes (Slevin and Ashburn 2011).

MEDICAL MARIJUANA

Approximately 40 years ago and beginning with Oregon in 1973, individual states began to decriminalize and legalize both the recreational and nonrecreational (i.e., "medicinal") use of marijuana. As of June 2014, 23 states have legalized

cannabis for medical use, with legislation authorizing the same pending in three states.

The Controlled Substances Act of 1970 categorized marijuana and its derivatives as Schedule I substances, indicating that in the opinion of legislators, cannabis had "a high potential for abuse," "no currently accepted medical use in treatment in the United States," and "a lack of accepted safety [standards] for use of the drug … under medical supervision." The case of *Gonzales v. Raich* (2005) involved DEA agents' destruction of medical marijuana plants. Two patients and two caregivers in California brought suit, arguing that in passing the Controlled Substances Act, Congress exceeded its constitutional authority under the Commerce Clause, which allows the federal government to regulate interstate commerce. In 2005, in reversing the Ninth Circuit's decision, the U.S. Supreme Court ruled that the DEA could continue to enforce the Controlled Substances Act "against" medical marijuana patients and their caregivers, even though these patients and their caregivers resided in states with authorized medical marijuana programs. In the light of this ruling, the role of physicians in recommending medical marijuana became exceedingly muddled, and physicians continue to face potential criminal prosecution for running foul of federal regulations. Also, because cannabis can impact negatively the physical and mental health of users and because there are few well-accepted medical indications for cannabis, physicians potentially are placed in the problematic situation of recommending a substance that has risks and benefits that are not understood fully.

In 2010, the American Society of Addiction Medicine (ASAM) published a series of findings, conclusions, and recommendations regarding medical marijuana in a "white paper." This paper assessed the therapeutic value of smoked marijuana and the role of physicians in the prescribing of marijuana for medicinal purposes. The ASAM paper asserted that physicians who were in a "gate-keeping role" in states where medical marijuana had been legalized should adhere to the "established professional tenets of proper patient care," including a history and good faith examination of the patient; the development of a treatment plan with objectives; the provision of informed consent, including discussion of risks, side effects, and potential benefits; a periodic review of treatment efficacy; consultation, as necessary; and proper record keeping that supports the decision to recommend the use of medical marijuana. In addition, the paper recommended that the physician have a "bona fide" physician–patient relationship with the patient, and that the physician have adequate training in identifying substance use disorders and addiction.

MALPRACTICE ISSUES

Malpractice complaints may allege that a physician's prescriptions for controlled substances have caused a patient's addiction or suicide attempt or that the patient was not adequately informed of the risks of the medications. Negligent (or nonexistent) assessment of a patient's substance abuse history or current status is one area of concern. Inappropriate treatment for substance abuse problems also may be alleged. Prescription of excessive amounts of controlled substances, or prescribing such medications to a known "addict," may result not only in medical board investigations and subsequent loss of licensure but also malpractice litigation against the physician. Therefore, it is crucial that physicians follow the previously discussed *Model Policy*'s criteria when treating high-risk patients.

Standards of care for prescribers of controlled substances are established both by case law and statute. In states such as New York, new statutory requirements generated by PDMPs will raise standards and expand potential bases for malpractice claims (e.g., negligence in failing to check PDMP database prior to prescribing controlled substances to a patient). The admissibility of information contained in PDMP databases in criminal or civil cases is currently unknown, however.

MEDICAL BOARD INVESTIGATIONS

Physicians with active substance use disorders may suffer impairments in reasoning and judgment that contribute to inappropriate diagnosis or treatment of patients or prescription of controlled substances to themselves. Sometimes, these physicians will prescribe controlled substances to patients with the understanding that the patient will then share the medication with or give the medication to the prescribing physician. Physicians engaging in such behavior also are more likely to engage in other boundary violations with patients, including sexual relationships, in order to obtain prescription drugs for personal use. Certain physicians with substance use disorders may come under investigation by a state medical board. Typically, a state medical board will receive a complaint regarding a possibly impaired physician from one of a variety of sources. Upon receiving the complaint, the medical board will conduct an initial investigation, which typically includes reviewing and possibly confiscating patient records, including prescriptions.

Some state medical boards may order an impaired physician into a "diversion" or "Physician Health Program" (PHP), with the goal of providing the physician with treatment for his or her substance use disorder (and monitoring his or her progress and ability to practice medicine), rather than meting out punitive sanctions. Typically, a physician's failure to comply with provisions of a PHP-mandated treatment plan would be reported to the state medical board for possible sanctions (e.g., license suspension or revocation). Perhaps because of the significant impact such sanctions can have on a physician's livelihood, PHPs have been remarkably effective in helping impaired physicians attain and maintain abstinence. McLellan et al. examined 16 PHPs in the United States from 1995 through 2001, and found that 5 years after entry into one of the programs, over 75% of physician were abstinent, still licensed, and still practicing medicine (McLellan et al. 2008).

SUMMARY

In order to effectively manage risk in their practices, physicians must keep abreast of not only the newest developments in medicine, but also of related changes in state and federal laws. To that end, the Federation of State Medical Boards is an excellent resource that can provide physicians with updated information on prescription drug regulations, including prescribing standards, for each state. Other sources of information include the DEA's requirements for prescribing controlled substances, Substance Abuse and Mental Health Services Administration (SAMHSA) resources (http://www.samhsa.gov), and FDA (http://www.fda.gov) resources.

In addition to remaining knowledgeable about current prescription standards and regulations, physicians should maintain practice policies and procedures consistent with the guidelines in the *Model Policy* in order to manage risk effectively and minimize the possibility of medical board sanctions, civil suits, or criminal prosecution.

SUMMARY KEY POINTS

- Prescription medication (particularly opioid) abuse is a growing problem in the United States and the source of many investigations and sanctioning of prescribing physicians.
- Practice standards (e.g., *Model Policy*) have been established to guide physicians in appropriate prescribing and management of patients on controlled substances.
- State medical board investigations may involve physicians being ordered to "diversion" programs, if personal substance use is involved in inappropriate prescribing claims.

Court oversight of psychotropic prescribing in youth in state custody

CORY JAQUES

INTRODUCTION

Over the past two decades, there has been a steady rise in the use of psychotropic medications to treat children and adolescents with emotional and behavioral problems (Zito et al. 2000). Public concern, often driven by media accounts, over the high rates of psychotropic medication use among youth in foster care has led to increased scrutiny about its appropriateness in this vulnerable population. Studies show that youth in state custody, including those in foster care and the juvenile justice system, have higher rates of psychotropic medication use, singly and concomitantly, than do youth who are eligible for Medicaid through income or disability qualifications (dosReis et al. 2001; Zito et al. 2008). Recent federal legislation also imposes increased oversight of prescribers to youth in state custody. These facts have led many states to adopt legislation requiring state agencies to monitor the treatment of children in their care. Practitioners have responded to these evolving standards, which are intended to promote the best care for young psychiatric patients in state custody. (For the purposes of this chapter, "youth in state custody" refers generally to two main groups of youth: those in foster care and those who are in various stages of an adjudication process managed by the juvenile justice system.)

In the United States, parents typically are the "guardians" of their children, and are authorized to direct their medical care, which includes decision making regarding psychiatric treatment and providing informed consent to such treatment (Feigenbaum 1992). When a minor is taken into state or county custody, the state or county must provide for the youth's basic health-care needs, including mental health and substance abuse treatment. However, medical services cannot begin without obtaining the appropriate consent for care. Entry into the foster care or juvenile justice systems does not automatically remove a parent's right to consent to their child's health care. For purposes of this chapter, when referring to youth in foster care or the juvenile justice system, the assumption is that parental guardianship has been temporarily or permanently terminated, and that the state has been appointed the legal guardian of, and assumed all parental responsibilities and decision making related to, the child.

Determining who may consent to health care for youth in state custody involves considering many different factors, many of which will vary by jurisdiction. In California, for example, the juvenile court has the authority to suspend a parent's right to consent to medical care once a minor has been adjudicated a ward or dependent of the court (California Welfare and Institutions Code §725). If the minor is declared a ward, the court may place him or her in a county facility, a group home, or home under parent or guardian supervision. Foster care placements include relatives, foster families, group homes, shelters, and other placements. Youth in the juvenile justice system include those who are residing in a detention center or in a community placement but are still under state supervision.

Increased need for mental health treatment for youth in state custody

Given the disruption in family bonds and high rates of traumatic exposures, it is not surprising that youth in state custody (either via the dependency of delinquency process) commonly experience social, emotional, and behavioral problems. The National Survey of Child and Adolescent Well-Being (NSCAW) revealed that youth involved in the child welfare system have disproportionately high rates of mental health problems, with approximately one-third of youth in foster care scoring in the "clinical" range on the Child Behavioral Checklist, a tool that assesses both internalizing and externalizing behaviors (U.S. Government Accountability Office 2011).

Another study showed that 63% of youth in foster care between the ages of 14 and 17 met criteria for one or more

mental health diagnoses at some point in their lives (White et al. 2007).

Several hypotheses have been put forward to attempt to explain the increase in psychotropic prescriptions in youth, and foster youth in particular. These include prescribers' utilizing flawed diagnostic methods, pathologizing normal behavior, succumbing to the influence of the pharmaceutical industry, failing to provide alternate psychosocial treatments, and not resisting financial incentives to medicate. Other possible contributing factors include poor access to therapists trained in evidence-based treatments, lack of coordination of available services, overall shortage of child psychiatrists, and insufficient state oversight of psychotropic prescribing to youth in state custody.

Concerns about the increased use of psychotropic medications for youth in state custody mirror emerging legal doctrine about standards of care required for these patients. As medical treatments evolved, with new and more sophisticated medications being developed, legal concerns about the rights of patients to refuse such treatment emerged, necessitating judicial involvement in those medical decisions.

Prevalence of psychotropic medication use among youth in foster care

Media accounts often conclude that youth in foster care are being "over-medicated" or inappropriately medicated (De Sa 2014). However, the disproportionately high rate of psychotropic medication use among youth in foster care likely reflects, at least in part, increased levels of emotional and behavioral distress in these youth. Although inappropriate prescribing certainly does occur, this can be minimized through careful medical implementation of the "best interests" standard.

Currently, there is no comprehensive source of data regarding psychotropic medication usage among youth in foster care. Most studies on the use of medications in this population utilize data from Medicaid claims and are often geographically specific. However, published studies consistently show higher rates of use among youth involved in the child welfare system than in socioeconomically matched youth in the general population.

The prevalence of psychotropic use for youth in foster care in community settings ranges from 14% to 30% (Zima et al. 1999; Raghavan et al. 2005; Zito et al. 2005), with significantly higher prevalence rates for youth in therapeutic foster care (67%) and group homes (77%) (Breland-Noble et al. 2004).

The U.S. Government Accountability Office (GAO) released a report in 2011, after examining the use of psychotropic medications in five states: Florida, Maryland, Massachusetts, Oregon, and Texas. This 2008 data, which include Medicaid claims for prescriptions of psychotropic medications, indicated that 21%–39% of youth in foster care received a prescription for a psychotropic medication compared to 5%–10% of youth not in foster care (U.S. Government Accountability Office 2011). Studies have identified several factors that influence the likelihood of psychotropic use among children in foster care (Raghavan et al. 2005):

- *Gender*: Males are more than two times as likely to receive psychotropic medications as females (19.6% versus 7.7%).
- *Age*: The likelihood that a child will receive psychotropic medication increases with age (3.6% of 2- to 5-year-olds, 16.4% of 6- to 11-year-olds, and 21.6% of 12- to 16-year-olds).
- *Placement type*: Youth in the most restrictive placement settings are the most likely to be taking psychotropic medications.
- *Behavioral concerns*: Youth scoring in the clinical range on the Child Behavioral Checklist are more likely to be taking psychotropic medications than those who score in the subclinical range.

The Agency for Healthcare Research and Quality (an agency within the U.S. Department of Health and Human Services) funded a study of antipsychotic prescribing based on Medicaid claims from 16 states. The study found that utilization of antipsychotics in 2007 was much higher among foster youth than among nonfoster youth—12.4% versus 1.4%, respectively (Rutgers Center for Education and Research 2010). Concomitant use of psychotropic medications (a.k.a., "polypharmacy") is also on the rise, with as many as 22% of youth prescribed two or more medications from the same class (Zito et al. 2008). Youth with autistic spectrum disorders in foster care are twice as likely to receive three or more medications than those eligible for Medicaid through a disability status (Rubin et al. 2009). Almost universally, of particular concern is the rapidly expanding use of second-generation antipsychotic medications, especially when they are prescribed to treat illnesses for which they are not usually indicated, including attention deficit hyperactivity disorder (ADHD) and conduct disorder (Crystal et al. 2009; dosReis et al. 2011).

Although Medicaid data provide abundant information about the use of psychotropic medications in foster youth, little data exist about the use of psychotropic medications among detained youth, who are generally not Medicaid-eligible while incarcerated. Existing studies analyze data from a particular state or local jurisdiction, and knowledge of general national trends in "juvenile justice" psychotropic prescribing is lacking.

Ideally, psychotropic medications are prescribed after a thorough assessment and, if appropriate, trials of psychotherapeutic or behavioral interventions. Such medications should decrease the frequency and severity of significant psychiatric symptoms and allow the youth to engage more fully in much needed psychotherapeutic treatment. However, for foster and detained youth (i.e., youth detained in juvenile justice facilities), information often is difficult to access and stepwise, algorithmic treatment may be neither pragmatic nor available. In these circumstances,

government regulation of prescribing practices, typically via an independent consultation with another psychiatrist, can be helpful and important.

Appropriateness of psychotropic medication use among children in foster care

In a comprehensive study, the Tufts Clinical and Translational Science Institute examined policies and practices concerning state oversight of psychotropic medication for children in foster care (Leslie et al. 2010). This study identified several patterns that may signal a "red flag" that factors other than clinical need are impacting the prescription of psychotropic medications. The most common red flags include instances when a child is prescribed too much medication, too many medications, or medication at too young an age.

A potential outlier practice that may be cause for concern is the prescription for medication in dosages that exceed recommendations. The Food and Drug Administration (FDA) establishes dosage guidelines for all medications. However, the majority of pediatric psychotropic use is off-label, and very few of the medications utilized have research-based guidelines for dosages in this population (Roberts et al. 2003). In the absence of robust, evidence-based prescription guidelines, some jurisdictions have adopted "practice parameters" to define safe and effective use of psychotropic medications, using a consensus-based approach (Naylor et al. 2007). Other jurisdictions have implemented systems that require pharmacy-based prior authorization in an effort to ensure proper use and dosage of psychotropic medications.

Another potential "red flag" is the use of multiple psychotropic medications concomitantly. Youth in state custody often have significant histories of maltreatment and trauma, resulting in multiple co-morbid diagnoses and complex mental health needs that may require multiple medications—often from more than one class—to adequately address mental health symptoms. A 2008 study of children in foster care revealed that 21.3% were prescribed psychotropic medication from one class, 41.3% from three or more classes, 15.4% from four or more classes, and 2.1% from five or more classes (Zito et al. 2008). Patterns that may be cause for concern include prescribing youth three or more medications at a time, or prescribing two or more medications within the same class for more than 30 days. In addition, prescribing multiple medications prior to adequately evaluating the efficacy of a single medication should raise a red flag.

The use of psychotropic medication to treat very young children is of particular concern, because this population may be especially vulnerable to adverse effects (Gleason et al. 2007). The previously referenced GAO study found that 0.3%–2.1% of children in foster care under the age of 1 year were prescribed medications that were potentially psychoactive—most commonly antihistamines and benzodiazepines—compared to 0.1%–1.2% of children not in foster care (GAO 2011).

Of all the categories of psychotropic medications used to treat mental illness in youth, second-generation antipsychotic medications have come under the most scrutiny, likely due to their potential for inducing serious side effects, including tardive dyskinesia, dystonia, and metabolic syndrome (e.g., hyperlipidemia, diabetes, weight gain, etc.). Over the past 20 years, there has been a dramatic rise in the use of second-generation antipsychotic medications for youth with mental health problems. A 2009 study found that youth in foster care were almost nine times more likely to be prescribed antipsychotic medications than other youth covered by Medicaid (Crystal et al. 2009). Although antipsychotic medications may be a legitimate and necessary treatment option for some youth in foster care, the use of these medications should be monitored closely. Patterns that may be cause for concern include prescribing youth antipsychotic medications for more than 2 years or prescribing this class of medication for illnesses other than schizophrenia, other psychotic disorders, or bipolar disorder.

LEGAL BACKGROUND

The recognition of the due process rights of children, as they relate to delinquency proceedings, began in earnest in the 1960s. In 1967, the U.S. Supreme Court clarified due process rights for juveniles facing delinquency charges. Gerald Gault, a 15-year-old, was taken into custody for making an obscene telephone call, and was subsequently found delinquent and sentenced to an indeterminate term at a state industrial school. In the decision *In re Gault,* the Supreme Court held that Gault was denied due process of law and that juvenile proceedings must meet the constitutional standards of due process and fair treatment guaranteed by the Sixth and Fourteenth Amendments, and previously believed by some to apply only to adults (*In re Gault* 1967). In light of the new evocation of children's rights, psychiatrists and state lawmakers adopted new protocols to ensure that patients' rights were not violated when admitted for psychiatric treatment and evaluation.

The psychiatric treatment of adults and children is regulated in all states through legislation that establishes guidelines for both voluntary admission and involuntary psychiatric evaluation and treatment. Some states distinguish between adult and juvenile patients, and others make distinctions based on the presence or absence of specific mental illnesses or drug and alcohol abuse (e.g., different involuntary commitment procedures). Regardless of the way by which patients are distinguished, each jurisdiction typically provides for short-term, emergency admissions, with procedures for involuntarily evaluating or hospitalizing patients.

The U.S. Supreme Court has consistently ruled that the Due Process Clause protects a competent adult's fundamental right to refuse unwanted medical treatment (*Cruzan v. Dir.*, Mo. Dep't of Health 1990). This protection applies

to persons with mental illness by allowing them to refuse "invasive" treatment, such as involuntary administration of psychotropic medication, even when the state may think such measures are in their best interest. When patients are children, their parents typically are authorized to direct their medical care, which includes making decisions regarding psychiatric treatment and providing informed consent to such treatments (Feigenbaum 1992). Informed consent is the process by which the treating health-care provider discloses appropriate information to a competent patient so that the patient may make a voluntary choice to accept or refuse treatment (Appelbaum 2007). In the United States, minor children are generally considered legally incompetent and thus unable to provide informed consent to accept or refuse most forms of medical treatment. In cases where an individual is deemed incompetent via judicial means, and thus incapable of giving informed consent as to their treatment, courts have developed two different standards that may be used in complying with informed consent; the substituted judgment standard and the "best interests" standard. These standards are discussed elsewhere in this textbook in more detail, but a brief examination of them here is informative.

These standards evolved out of new constitutional requirements relating to psychiatric care. In *Mills v. Rogers*, the U.S. Supreme Court held that, with respect to incompetent persons, a judicial determination of substituted judgment was required before the administration of drugs (*Mills v. Rogers* 1982). That substituted judgment required a court to balance differing interests; in other words, the substitution of the state's judgment for the individual's had to be based on specific facts. In applying the balancing test (i.e., balancing the individual interest versus state interest) the Court held that involuntarily committed patients had a liberty interest in refusing medications and that this interest could be superseded only when outweighed by the state's interests. In applying the substituted judgment standard, the decision maker is required to "ascertain the incompetent person's actual interests and preferences" and to attempt to make the decision that an incompetent person would make if he or she were competent (*Mills v. Rogers* 1982).

Substituted judgment does not apply to children because they have never been "competent." Instead, their parents' judgment is substituted. In those cases, a new standard was developed to determine the appropriateness of medical treatment. To protect the due process rights of children, Courts looked to the best interests of the child in making decisions about medical treatment, including treatment with psychotropic medications. This is especially true for youth in state custody, because in those cases, the state acts "in loco parentis." The "best interests" standard reflects the idea that the treatment decision made on a legally incompetent patient's behalf should advance that individual's best interests. Therefore, this standard requires that decisions about the administration of medication be made based on the patient's best interests. Unfortunately, the legal decision maker (i.e., judicial officer) is not equipped to make decisions about specific psychiatric treatment options and how a child's best interests are best served under this test. Consequently, courts increasingly rely on treating physicians to help guide their decisions.

STATUTORY BACKGROUND

In addition to the due process standard created by the courts, Congress and the states have provided both the means and regulations for some types of psychiatric treatment. The Social Security Act (SSA), enacted in 1935, is a social welfare legislative act that created the Social Security system in the United States (Social Security Act 1935). The *Stephanie Tubbs Jones Child Welfare Services Program* (Title IV-B, Subpart 1 of the Social Security Act) provides grants to state and tribal agencies to develop programs directed toward the goal of keeping families together. These funds, often combined with state and local governments, as well as private funds, are directed to accomplish the following purposes: protect and promote the welfare of all children; prevent the neglect, abuse, or exploitation of children; support at-risk families through services that allow children, where appropriate, to remain with their families or return to their families in a timely manner; promote the safety, permanence, and well-being of children in foster care and adoptive families; and provide training, professional development, and support to ensure a well-qualified workforce.

The *Fostering Connections to Success and Increasing Adoption Act of 2008* amended title IV-B, subpart 1 of the Social Security Act to require state and tribal title IV-B agencies to develop a plan for ongoing oversight and coordination of health-care services, including mental health care, for youth in foster care (*Fostering Connections to Success and Increasing Adoptions Act* 2008). The intent of this act was to ensure that youth in foster care receive quality health-care services, including appropriate oversight of prescription medications (§422(b)(15) of the Act).

The Child and Family Services Improvement and Innovation Act of 2011 amended the law by adding to the requirements for the health-care oversight and coordination plan (§422(b)(15)(A)(ii) and (v) of the Act). This Act expands the requirements of the previous federal code by mandating that states amend their Title IV-B state plan to identify appropriate use and monitoring of psychotropic medications. In addition, states are required to use both training and technical assistance to oversee psychotropic prescribing and to document these efforts in their strategic child welfare systems' plans. In these plans, each state must include an outline of procedures to monitor and treat "emotional trauma" associated with a child's maltreatment and removal from his or her home, and protocols for the appropriate use and monitoring of psychotropic medications. The Children's Bureau has instructed states to address the following areas: (1) comprehensive and coordinated screening, assessment, and treatment planning; (2) informed and shared decision making and methods for ongoing communication between the prescriber, the child, his or her caregivers, and all other

service providers; (3) effective medication monitoring; (4) availability of consultation by a board-certified or board-eligible child and adolescent psychiatrist; and (5) mechanisms for accessing and sharing accurate and up-to-date information and educational materials related to mental health and trauma-related interventions.

In April 2012, the Administration on Children and Families (ACF) released the Information Memorandum, "Promoting the Safe, Appropriate, and Effective Use of Psychotropic Medications for Children in Foster Care," to serve as a resource to State and Tribal title IV-B agencies as they comply with requirements to develop protocols for the appropriate use and monitoring of psychotropic medications, which were established by the Child and Family Services Improvement and Innovation Act (U.S. Department of Health and Human Services 2012). To help states create and implement oversight protocols, ACF convened a summit in August 2012: "Because Minds Matter: Collaborating to Strengthen Management of Psychotropic Medications for Children and Youth in Foster Care." This summit brought together representatives/leaders from the child welfare, Medicaid, and mental health systems from all 50 states, the District of Columbia, and Puerto Rico.

In order to meet the new statutory requirements set forth in the Child and Family Services Improvement and Innovation Act of 2011, state agencies have utilized different approaches. One approach is to devise and implement parameters that automatically trigger a "prior authorization" process or require expert consultation before a prescription can be filled. Most states also have developed psychiatric consultation hotlines to assist primary care physicians in making their treatment decisions. Some states will not reimburse doctors who do not follow the recommendations of the psychiatric consultant. Another approach is to keep Medicaid prescription registries in order to analyze the prescribing patterns of physicians and determine the "top prescribers" of antipsychotic medications. As of the writing of this chapter, the states with the most comprehensive and collaborative plans appear to be Florida, Maryland, Massachusetts, Minnesota, and Texas, all of which have detailed websites to provide information to physicians prescribing psychotropic medications to children and adolescents (Medicaid 2012).

PRACTICE GUIDELINES

A variety of policy statements and practice guidelines have been developed to guide and inform physicians treating youth in the foster care and juvenile justice systems. Examples include policy statements developed by the American Academy of Pediatrics (2002) and the American Academy of Child and Adolescent Psychiatry (AACAP n.d.). In addition, the practice parameters developed by the Texas Department of State Health Services are often used as a model for agencies seeking to improve their monitoring and oversight practices (Texas Department of State Health Services 2007). The AACAP statement proposes several guidelines to assist state and county agencies in developing programs and procedures for monitoring the use of psychotropic medications for youth in state custody. The standards are categorized as Minimal, Recommended, and Ideal.

A "Minimal" standard recommended by AACAP is that state child welfare agencies, the juvenile court, or other state or county agencies empowered by law to consent for youth to treatment with psychotropic medications should design and implement effective oversight procedures that include guidelines for the use of these medications for youth in state custody. A "Recommended" standard includes implementing a program that provides consultation by child and adolescent psychiatrists to the agency or persons that is/are responsible for consenting for youth to receive treatment with psychotropic medications. An "Ideal" program would include, among other things, the following:

- An advisory committee to oversee a medication formulary and provide medication-monitoring guidelines to practitioners who treat children in the child welfare system.
- Monitoring the rate and types of psychotropic medication usage and the rate of medication adverse events among youth in state custody.
- A process to review nonstandard, unusual, and/or experimental psychiatric interventions with children who are in state custody.
- Collecting and analyzing data regarding the rates and types of psychotropic medication use. This data should be available to clinicians in the state to improve the quality of care provided.

STATE-SPECIFIC EXAMPLE OF COURT AUTHORIZATION

In California, when a dependent child has been removed from parental custody, only the court has the authority to consent to the administration of psychotropic medication and may do so only upon a physician's request (California Welfare and Institutions Code §369.5(a)). In emergencies, psychotropic medications may be administered without court authorization. Briefly, an "Application Regarding Psychotropic Medication" (JV-220) must be completed and filed with the court and proper notice provided to the relevant parties and their attorneys. This includes notice to the minor, the minor's current caregiver, and the minor's parent or prior legal guardian, among others.

When submitting a JV-220 to the court, the prescribing physician is required to include a statement that addresses all of the following:

- The diagnosis of the child's condition that the physician asserts can be treated through the administration of the medication.
- The specific medication recommended, with the recommended maximum daily dosage and length of time this course of treatment will continue.

- The anticipated benefits to the child of the use of the medication.
- A description of possible side effects of the medication.
- A list of any other medications, prescription or otherwise, that the child is currently taking, and a description of any effect these medications may produce in combination with the psychotropic medication.
- A description of any other therapeutic services related to the child's mental health status.
- A statement that the child has been informed, in an age-appropriate manner, of the recommended course of treatment, the basis for it, and its possible results. The child's response must be included.

Upon receiving the completed JV-220 application, the court has 7 court days to approve the medication request, deny it, or order a hearing on the issue. Because this is a particularly complicated and sensitive matter, many counties have implemented their own protocols and local court rules regarding the JV-220 process. For example, in Los Angeles County, Juvenile Court Mental Health Services' clinicians (including pharmacists and physicians) review requests for court authorization and make a written recommendation as to the propriety of the proposed treatment based on information submitted on the JV-220 and, if necessary, review of collateral information.

SUMMARY KEY POINTS

- Psychotropic medications can be an important component of a comprehensive treatment plan to address the often-complex mental health needs of youth in state custody, including those in the foster care and juvenile justice systems.
- Some clinicians' current psychotropic medication prescribing patterns to treat these youth may not comport with evidenced-based practice standards that are generally supported by empirical research. Therefore, these prescribing patterns may violate the "best interests" legal standard of youth under these psychiatrists' care.
- Increased oversight of psychotropic medication prescribing is necessary to safely and effectively treat the mental health needs of these youth.
- State oversight systems, such as those highlighted in the Tufts report, may include such components as access to up-to-date guidelines on clinical practices and appropriate medication monitoring for youth in foster care and juvenile justice.

Forensic evaluation and treatment in the criminal justice system: Introduction

ALAN R. FELTHOUS

INTRODUCTION

As the "collective institutions through which an accused offender passes until the accusations have been disposed of or the assessed punishment concluded" the criminal justice system has three components: "law enforcement (police, sheriffs, marshals), the judicial process (judges, prosecutors, defense lawyers), and corrections (prison officials, probation officers, parole officers)" (Garner 1999, 381). Criminal forensic psychiatry is most relevant to the second component, the judicial process. Accordingly, this section addresses jail diversion programs, criminal competence, treatment for restoration of competence, criminal responsibility, post-adjudication evaluations and disposition of insanity acquittees, and presentencing evaluations. Correctional psychiatry constitutes a separate section of this volume.

Criminal law, of course, deals with crimes, a crime being defined as "[a] social harm that the law makes punishable; the breach of a legal duty treated as the subject-matter of a criminal proceeding" (Garner 1999, 377). Specific crimes are codified into statutory law by state and federal legislatures, with most states codifying their penal laws only once or twice a century and amending specific sections in the interim (Glaser 1974).

Criminal forensic psychiatry, including each of the topics addressed by the chapters in this section, begins with several legal contexts: the development of criminal law apart from civil law, the moral and legal importance attached to criminal intent and *mens rea*, codification of the criminal law in the United States, and criminal procedures requiring psychiatric assessments. Finally some recent developments in criminal forensic psychiatry are highlighted, including the potential and actual relevance of the still evolving technologies of neuroimaging and the Internet.

THE EMERGENCE OF CRIMINAL AS DISTINCT FROM CIVIL LAW

In early English law today's distinction between crime of criminal law and tort of civil law did not exist. Historians of criminal law concluded that criminal law evolved from the desire for revenge of the blood feud (Sayre 1931–1932). In the era of trial by battle and ordeal, early laws to emerge were based on strict liability, and criminal intent was not an element of a criminal offense prior to the twelfth century (Sayre 1931–1932). Neither was the distinction between felonies and misdemeanors what it is today. Prior to Bracton in the twelfth century, minor offenses were punishable by corporal punishment or amercement, and the distinction between civil and criminal aspects of trespass, between the misdemeanors and torts of today, was obscure (Sayre 1931–1932).

Only killings in self-defense or "by misadventure" were considered for royal pardon. In the centuries that followed, those who killed without guilty intent would also be relieved of criminal responsibility. The first statutory requirement of "malice aforethought" appears to have been articulated in a decree by Richard II in the fourteenth century (1389), intended to curb too liberally granted royal pardons: "[N] o charter or pardon shall be henceforth allowed before any justice for murder, the death of a man killed by making assault or malice prepense (*ou malice purpense*)" (Stephen 1883, 43, original in French).

Some crimes came under jurisdiction of canonical law, whereas other more serious crimes were dealt with by the secular government. Statutes enacted at the end of the fifteenth and beginning of the sixteenth centuries specified which types of homicide were excluded from "benefit of the clergy" (p. 996). Felonious homicide with malice aforethought was not clergyable and was punishable by death; whereas felonious homicide without malice aforethought was clergyable, subject to no more than a year of

imprisonment and branding of the thumb (Sayre 1931–1932), and became known as manslaughter.

Originally "malice" referred to the homicidal motive as a "general malevolence or cold-blooded desire to injure" (Sayre, 1931–1932, 997). Eventually the meaning was broadened such that it was no longer a purely psychological element. Coke, in his *Third Institute* (1669, defined murder as an unlawful killing "with malice fore-thought, either expreſſed by the party, or implied by law" (Coke 1669, 47). Malice aforethought came to be the qualities that distinguished more serious from less serious felony homicides, some but not all qualities of which actually pertained to *mens rea*.

Hale (1736) in the eighteenth century drew a distinction between sanity in civil and criminal wrongdoing, respectively. The particularization of *mens rea* into specific types of criminal offenses developed somewhat differently for crimes of homicide, larceny, burglary, and arson. At the beginning of the thirteenth century, murder and manslaughter and voluntary and involuntary homicide were not legally distinguishable (Sayre 1931–1932).

In the United States as in England, malice aforethought distinguished murder from homicide (Kadish et al. 2012). Unlawful or criminal homicide is graded in severity with different names, e.g., murder and manslaughter, and with different degrees, first-degree and second-degree murder. Each state further grades criminal homicide following this general scheme.

Crimes are either felonies or misdemeanors. In early English law, felonies were defined, by Blackstone for example, as "every species of crime, which occasioned at common law the forfeiture of lands or goods" (Blackstone 1979 [1769], 94). In contrast to misdemeanors, felonies are serious or major crimes and include arson, burglary, murder, and rape. Today a felony is considered to be a crime that is "punishable by imprisonment for more than a year or by death" (Garner 1999, 633), the imprisonment typically occurring in a state or federal prison. A misdemeanor, minor crime, or summary offense is in contrast to a felony usually "punishable by fine, penalty, forfeiture, or confinement [usually for a brief time] in a place other than prison [such as a county jail]" (Garner 1999, 1014).

CRIMINAL INTENT AND SPECIFIC *MENS REA*

The requirement for criminal intent in English law is traced back to a sermon by St. Augustine on James 5:12: "swear not neither by heaven neither by the earth, neither by any other oath" (Sayre 1931–1932, note 30, 984). Supporting the requirement of intent in the offense of perjury, St. Augustine declared that a man is a perjurer in the eyes of God if he testifies, out of self-interest, that it rained in a particular spot, when he believes it did not rain there (Sayre 1931–1932, note 30, 983–984). This principle of "*reum non facit nisi mens rea*" was recited in the *Leges* of Henry I: "A person is not to be considered guilty unless he has a guilty intention" (*Leges*, p. 94, *Henrici Primi*, c. 5, §28,95), even though elsewhere the text supported absolute criminal liability (88,6a, 270, -70, 126, 222, 90, 11a, 282). From this, Coke in the *Third Institute* (1669, p. 107) formulated the *mens rea* requirement as "*actus non facit reum nisi mens sit rea*" (the act is not criminal unless the intent is criminal), which he repeated as accepted law in the mid-seventeenth century (Sayre 1931–1932, note 51, 988).

Important in criminal law and forensic psychiatry is the dichotomy of specific versus general intent crimes. In a general intent crime, the individual simply did what he or she intended, i.e., the criminal act (Kadish et al. 2012). A specific intent crime is defined as one in which the actor had "the intent to accomplish the precise criminal act that one is later charged with" (Garner 1999, 814). Examples of specific intent crimes include assault, burglary, conspiracy, embezzlement, false pretenses, forgery, robbery, and solicitation. The specific intent is an element of the *mens rea* that the prosecution must prove beyond a reasonable doubt in order to gain a conviction. This type of *mens rea* requiring specific intent, also termed "special" or "positive" *mens rea*, pertains to the grading of offenses (Gilles Phillips and Woodman 2008). "[S]pecific intent crimes require proof of a particular mental state beyond the mere intent to engage in the proscribed conduct" (Gilles Phillips and Woodman 2008, 490).

The offense of burglary, as an example of a specific intent crime, requires not only unlawful entry but the intent to commit another felonious act once inside the building. Assault with intent to kill requires, as the name of the offense indicates, that the assault was committed with the specific intent of killing the victim (Kadish et al. 2012). If the specific intent is not proven, conviction of a lesser included offense such as a general intent crime, in these cases trespass and battery, respectively, can be the adjudicated outcome.

To prove beyond a reasonable doubt a defendant's specific purpose, in the same sense that the act is proven, would often be an insurmountable challenge for the prosecutor. The Supreme Court has addressed this issue with the distinction between mandatory and permissive presumptions. A mandatory presumption is one that the jury must accept unless there is evidence to the contrary. "A person of sound mind and discretion is presumed to intend the natural and probable consequences of his acts, but the presumption may be rebutted" (*Francis v. Franklin* 1985, 309). In some cases, however, inferences must constitutionally be permissive; the U.S. Supreme Court upheld the District Court's jury instruction: "[p]ossession of recently stolen property, if not satisfactorily explained, is ordinarily a circumstance from which [the jury] may reasonable draw the inference and find, in the light of the surrounding circumstances shown by the evidence in the case that the person in possession knew that the property had been stolen" (*Barnes v. United States* 1973, 839, 840).

CODIFICATION OF PENAL LAW

A most impactful development in the twentieth century has been the American Law Institute's (ALI) Model Penal Code (Official Draft, 1962, reproduced in Appendix of Kadish et al. 2012, 1191–1253). Committed to simplifying, clarifying, and improving the administration of justice, prominent academics, lawyers, and judges founded the ALI in 1923. The move away from common law toward "codification" had its roots in the values of Jeremy Bentham (1780, 2007) who coined the term and espoused a system of rational, deterrent rather than retributive law that maximized benefit for most people (Kadish 1987). Supported by the essays on positive law by John Austin (1832 and 1863, 1954), by mid-twentieth century the Benthamite tradition of replacing judicial law with legislation had become widely accepted and practiced. After 1950 a series of tentative model penal code drafts were produced under the leadership of Professors Herbert Wechsler and Louis B. Schwartz. The 1962 Official Draft had unprecedented effect, with 34 states adopting some elements of the Model Penal Code over the next 20 years (Kadish et al. 2012, 1191).

CRIMINAL JUSTICE PROCEDURAL CONTEXT OF FORENSIC EVALUATION

The criminal forensic psychiatrist will be well aided by a general knowledge of criminal justice procedures to appreciate contextual aspects and limitations of his role as well as sources of information for his evaluation of a defendant. The investigation of a criminal offense involves interviewing suspects, witnesses, and victims and gathering physical evidence. In most cases the only clue to an offender's identity is personal identification by a victim or witness. Only 39% of violent offenses (murder, aggravated assault, forcible rape, and robbery) are cleared by arrest in cities with a population exceeding one million, and only 13% of serious property crimes (Kadish et al. 2012, citing FBI crime statistics for 2009).

Of those cases cleared by arrest about one-half are dismissed. Reasons for dismissal include that the suspect was not guilty, guilt could not be proven, police and prosecutors were too busy with other cases, or the offender had emotional or social problems better handled by another agency. In some jurisdictions charges were dismissed after the defendant successfully completed a pretrial diversion program (Kadish et al. 2012).

After arrest the suspect is brought before the magistrate, and many are released within 24 hours of arrest. The magistrate decides whether to release the defendant before the trial. More than 90% of convictions in most jurisdictions are secured by the defendant's plea of guilty, often resulting from either a hurried or prolonged negotiation between prosecutor and defense counsel (Kadish et al. 2012).

By pleading guilty a defendant waives three principal rights: the privilege against self-incrimination, the right to a jury trial, and the right to confront one's accuser. These three waived rights, elements of the offense, and the potential sentence are made explicit in open court with the judge, who must determine that the choice to plead guilty was "knowing and intelligent" (*Brady v. United States* 1970; Kadish et al. 2012).

Only a small fraction, perhaps 4% of all cases filed, actually proceeded to trial, and in one series, only 1% were acquitted (Givelber 2005). Others are disposed of by guilty pleas, dismissal, or pretrial diversion (Kadish et al. 2012). Yet the outcomes of trials and appeals court hearings serve to establish standard procedures; practices in arresting, charging, dismissing, diverting pretrial, and plea bargaining, in other words, standards for many other cases that never reach trial (Kadish et al. 2012). Sentencing can seem quite informal compared with the high formality of the trial in chief to determine guilt. Figure 25.1 illustrates the potential routes by which cases move through the criminal justice system and points of potential intercession by forensic psychiatry.

If the main goal of the criminal judicial process is to prosecute and sanction, equally important goals are to ensure that the process is fair and the outcome is just. A number of protections have been adopted to ensure that the process is fair, for example, the exclusionary principle that excludes the use of evidence at trial that was obtained by the government in a manner that violated the defendant's constitutional rights (Stone 2003). Each of the themes addressed in this section is concerned with fairness for the defendant, ultimately the *raison d'être* for psychiatric involvement, fairness that is usually required by the Due Process Clause of the Fourteenth Amendment.

The primary basis for constitutional regulation of criminal procedure is the Bill of Rights, the first Ten Amendments to the U.S. Constitution (Goldstein 2003). Except for the prohibition against excessive bail and the right to a grand jury indictment in felony cases, all of the procedural rights of the first Ten Amendments have been applied to the states via the Due Process Clause of the Fourteenth Amendment. As specified by the U.S. Supreme Court, every state's criminal procedures must conform to the U.S. Constitution (Goldstein 2007).

Especially where the consequence for the defendant is state-imposed punishment, the government does not require a person to be able to do something for which he or she is incapable. Thus, a person should not be convicted and punished for committing a crime that he or she was incapable of committing (Felthous 2008). Neither should the person be tried, convicted, and punished if he or she lacked any of a number of adjudicative competencies (Felthous 2008, 2010), including competence to waive *Miranda* rights, to plead guilty, to waive representation by counsel, to represent oneself without counsel, to waive into adult court for juveniles, to waive a jury trial, to waive appeals, to be sentenced, to be executed (Miller 2003), and various other subspecies of adjudicative competence in the broad sense (Perlin 2003).

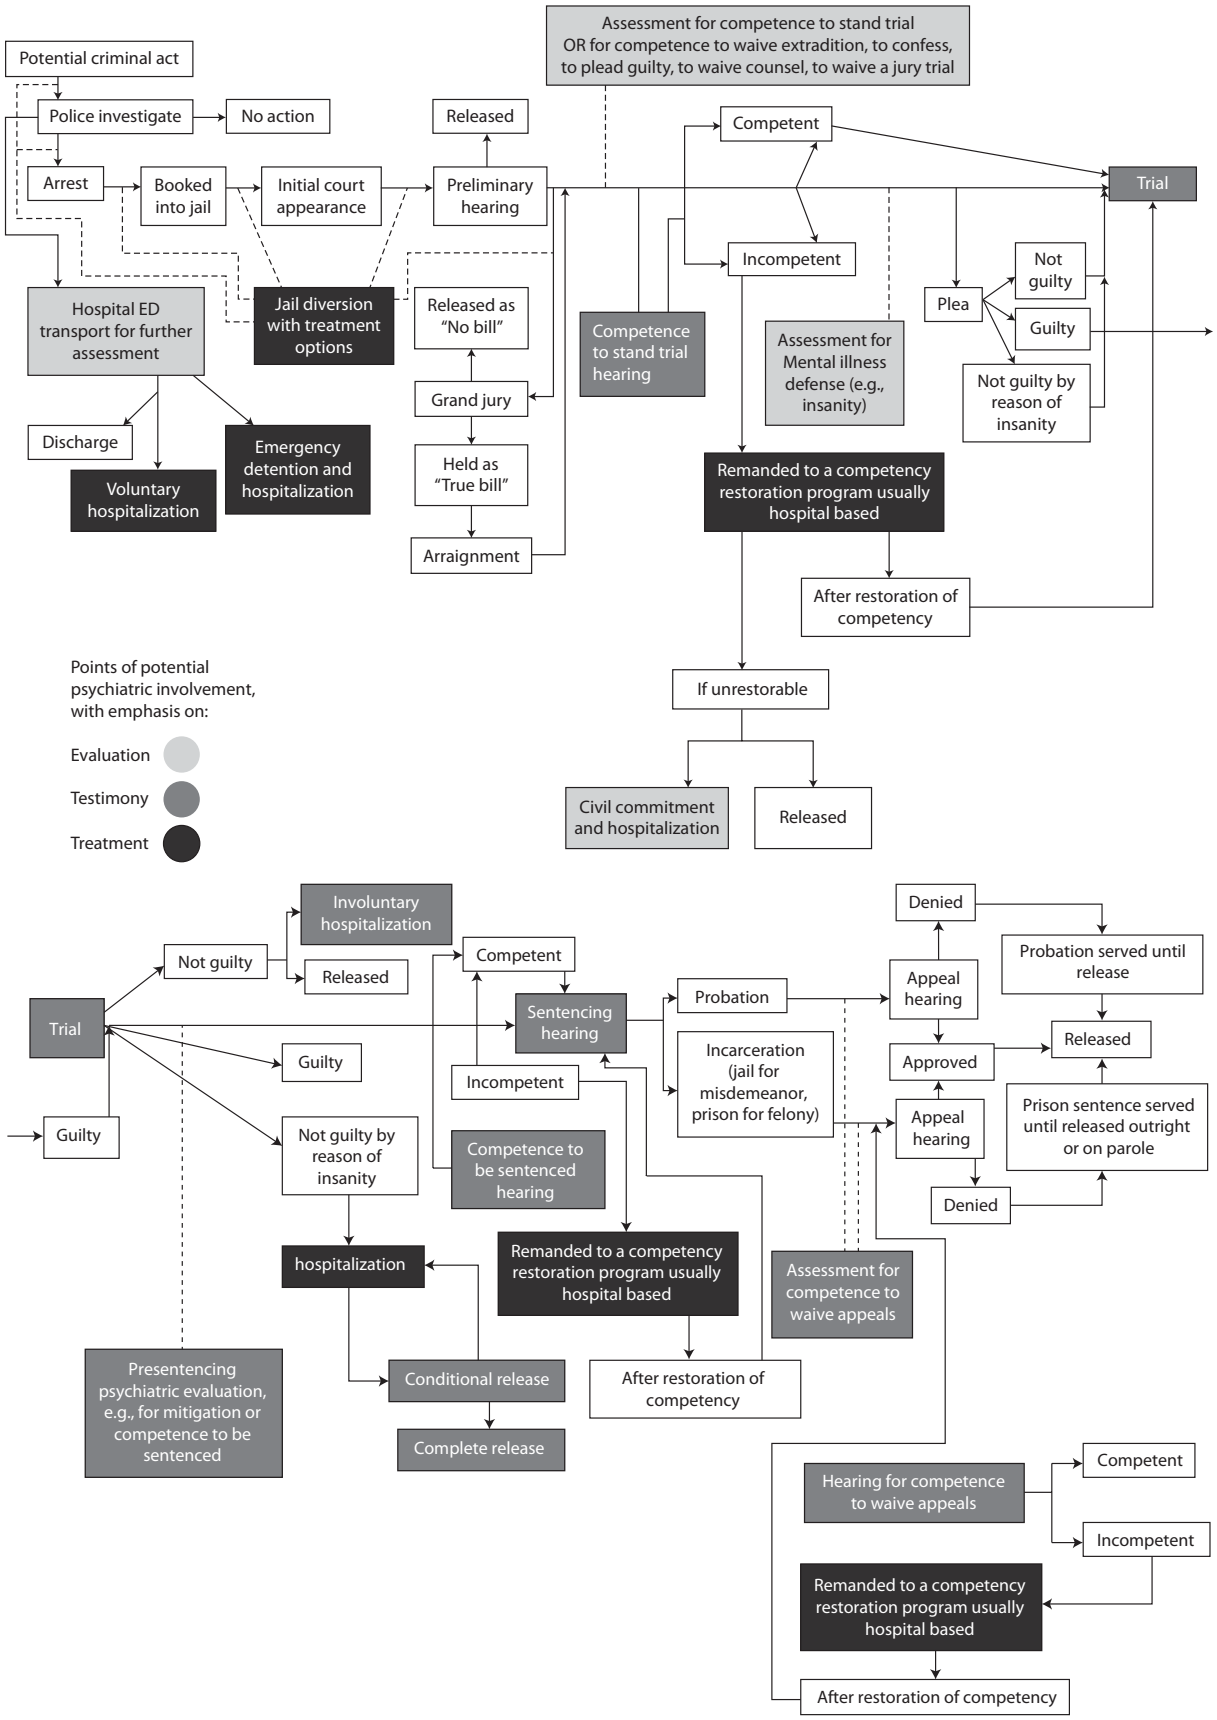

Figure 25.1 The pathways that a criminal defendant can progress through the criminal justice system with potential point of forensic psychiatric participation denoted.

It is the quest for fundamental fairness that brings psychiatric testimony into the criminal courtroom. The U.S. Supreme Court has based its most relevant holdings in this regard on the Due Process Clause of the Fourteenth Amendment. All of the following rights involving psychiatric expertise are based on the Due Process Clause: the defendant's right not to be tried or convicted while incompetent to stand trial (*Dusky v. United States* 1960; *Pate v. Robinson* 1966), reaffirmed in subsequent decisions addressing other aspects of the issue (e.g., *Drope v. Missouri* 1975); treatment for restoration of competence, i.e., the incompetent defendant must have his or her competence restored before he or she faces trial (*Drope v. Missouri* 1975); the standard of proof for the defendant to establish his or her incompetence can be no greater than preponderance of the evidence (*Cooper v. Oklahoma* 1996); a defendant's qualified right to refuse psychotropic medication prior to trial (*Riggins v. Nevada* 1992); the principle that involuntary treatment for restoration of competence must be medically appropriate and must be administered appropriately (*Riggins v. Nevada* 1992; *Sell v. United States* 2003); and treatment for restoration of competence to stand trial cannot be indefinite, also supported by the Equal Protection Clause (*Jackson v. Indiana* 1972). Conditions under which a defendant can be medicated involuntarily for restoration of competence are also regulated by the Due Process Clause (*Sell v. United States* 2003).

The Supreme Court has not ruled that the Due Process Clause requires availability of an insanity or other mental defense. Noting that the Supreme Court never supported abolition of the insanity defense, the Nevada Supreme Court determined that the insanity defense was so rooted in our notions of justice as to be a fundamental right protected by the Constitution (*Finger v. State* 2001). In a footnote in its *Clark* decision the High Court wrote "[W]e have never held that the Constitution mandates an insanity defense, *nor have we held that the Constitution does not so require*" (*Clark v. Arizona* 2006, note 20, 2722). Thus, although the Supreme Court has not interfered with state insanity jurisprudence, including abolition of the insanity defense, within this footnote it left the door open for future consideration. State law must nonetheless comport with the U.S. Constitution that provides defendants with the right to present evidence (*Crane v. Kentucky* 1986). Expressed more explicitly, "Whether rooted directly in the Due Process Clause of the Fourteenth Amendment or in the Compulsory Process or Confrontation Clauses of the Sixth Amendment," in his dissent in *Clark* Justice Kennedy stated, "the U.S. Constitution guarantees criminal defendants a meaningful opportunity to present a *complete* defense" (italics added, 2743, *Clark v. Arizona* 2006).

Throughout the various required competencies, especially the competency to commit a crime as defined by a jurisdictional insanity defense (Morse 1999) or adjudicative competencies best exemplified by the *Dusky* standard for competence to stand trial (*Dusky v. United States* 1960; see Felthous 2011), and competence to be executed (*Panetti v. Quarterman* 2007), rational thinking is required. It is true that most statutory CST standards and various less commonly applied competencies do not explicitly require rationality. Nonetheless, state CST standards would claim to comport with constitutionally required rationality (e.g., Dierker 2014, §11:12, 1., c., 138), and if a key mental element was lacking to achieve competency, such as the capacity to assist in one's defense, then the missing element was also missing in rationality. Specific standards require more than just rationality in defining the particular competence of concern, but rationality is certainly a theme in the various competencies required throughout the criminal justice process.

RECENT DEVELOPMENTS IN CRIMINAL FORENSIC PSYCHIATRY

Rosner (2003, p. 3), citing the Standards for Fellowship Programs in Forensic Psychiatry (Joint Committee on Accreditation of Fellowships in Forensic Psychiatry 1982) defined criminal forensic psychiatry so as to include "at a minimum, competence to stand trial, competence to enter a plea, testimonial capacity, voluntariness of confession, insanity defense(s), diminished capacity, sentencing considerations, release of persons who have been acquitted by reason of insanity."

Much has occurred in the realm of criminal forensic psychiatry since the Second Edition in 2003. First, tribute is well due to our friend and colleague Robert Miller who passed in the interim. His indefatigable and meticulous scholarship as editor of the criminal law section in the first and second editions (Miller 1994, 2003) provided an enduring, thorough, and well-referenced model for this section on forensic psychiatry.

It may not be hyperbole to suggest that the past decade has had the most substantive developments in the field of criminal forensic psychiatry of any other decade in the past. From the American Academy of Psychiatry and the Law (AAPL), forensic psychiatrists now have the benefit of the insanity practice guideline (AAPL 2014) complementing the earlier guideline on competency to stand trial forensic assessments (Mossman et al. 2007). Just published for the first time is the AAPL guideline for forensic assessments with subsections on gathering information on criminal cases, presentencing evaluations, and other topics relevant to both criminal and general forensic psychiatry (Glancy et al. 2015). The fifth edition of the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* was published in 2013. Additional landmark cases have shaped the law and provided further instruction for the proper practice of criminal forensic psychiatry. Considerable relevant scientific contributions are to be found in books and journals published over the past decade.

The digital technologies of neuroimaging and the Internet are gaining increasing relevance to criminal forensic psychiatry. Neuroimaging evidence is increasingly coming into evidence in criminal trials, but with considerable circumspection and reservation (Martell 2009). Magnetic

resonance imaging (MRI), and computed tomography (CT) scans have routinely been admitted into evidence to demonstrate trauma and disease, whereas positron emission tomography (PET), single-photon emission computed tomography (SPECT) scans, and functional MRI (fMRI) studies are not so readily admitted (Moriarty 2008). In his review, Martell concludes that the use of structural brain imaging is empirically supported for providing evidence of brain lesions resulting from certain neurological disorders, traumatic brain injury, or stroke. Of the functional brain imaging techniques, PET can assist in the differential diagnosis of dementia, identification of brain tumors, and further assessment of temporal lobe epilepsy. SPECT is well established for the diagnosis of suspected brain trauma, epileptic foci, dementia, and cardiovascular disease. Martell (2009) cautions against using neuroimaging evidence to directly address violent or criminal behavior and to diagnose or confirm nonneurological psychiatric disorders such as disorders of mood, thought, or developmental disorders (Martell 2009).

In certain cases, PET has been admitted into evidence to show evidence of diminished impulse control and cognition as well as traumatic and toxic brain injury (Moriarty et al. 2013). As a brain imaging technique used to show impaired brain function, PET evidentiary application appears to have resulted in offense reduction through jury adjudication (*People v. Williams* 2004) or plea bargaining (*People v. Weinstein* 1992). Moriarty and colleagues (2013) conclude that courts are admitting neuroscientific evidence such as PET without an analysis of reliability, much like other behavioral science testimony.

Neuroimaging can be persuasive to a jury, as demonstrated empirically with mock jurors (Gurley and Marcus 2008). The relevant AAPL guideline cogently concludes that imaging procedures can be helpful in diagnosing certain brain disorders but not in establishing the functional criteria of the insanity defense (Giorgi-Guarnieri et al. 2014).

Today it behooves the forensic evaluator to inquire about a criminal defendant's computer literacy and particular uses of the Internet. As cataloged by Recupero (2010), there are a variety of criminal activities that one can engage in on the Internet. The Internet can also be used to facilitate criminal activity (McGrath and Casey 2002). Such activities can lead to specific charges and assessments for criminal responsibility. An emerging literature raises the possibility of computer or Internet psychopathology such as Internet Gaming Disorder, not an official *DSM* diagnosis at this time (American Psychiatric Association 2013). The defendant may have accessed the Internet in order to prepare for the forensic interview such as by Googling the evaluator. Of special relevance to evaluation for criminal responsibility are revelations that the defendant might have made on the Internet that reflected his or her violent fantasies and intentions. This is becoming better appreciated in the study of individual mass killers and terrorists, especially lone terrorists (Meloy and Yakeley 2014; Post et al. 2014), but this is also observed in more plebian offenders. What at first may appear to represent a bizarre delusional system woven together out of whole cloth can turn out to be "supported" by similar or identical fantasies and potential content for belief systems, which the defendant accessed on the Internet. In such cases the evaluator must consider whether the defendant's beliefs are delusional or represent a "subcultural" set of beliefs, perhaps entertained only by certain Internet users, a "virtual" subculture as it were.

A few changes in this section should be noted: as the section title indicates, treatment within the criminal justice system is as important as forensic assessments. Accordingly, chapters on jail diversion programs and the treatment and restoration of competence to stand trial are added. Also important to criminal forensic psychiatry are presentencing evaluations and post-adjudication dispositions. The chapters on competence to stand trial and criminal responsibility incorporate recent clinical, scientific, and legal developments with the aim of providing the most current, explanatory, and practical information.

Jail diversion, specialty court, and reentry services: Partnerships between behavioral health and justice systems

DEBRA A. PINALS

INTRODUCTION

There is a growing recognition and discourse surrounding the high prevalence of individuals with mental illness and co-occurring substance use conditions in the criminal and juvenile justice systems. A 2006 report of the Bureau of Justice Statistics showed that at midyear 2005, more than half of those incarcerated in jails and prisons had some type of history of mental health problems, and of those with a mental health problem, approximately three-quarters had a co-occurring substance use problem (James and Glaze 2006). Numerous studies have examined these issues. It has generally been stated that approximately 10%–15% of jail and prison inmates have some form of mental disorder that requires treatment (Hoge et al. 2009). Additionally, men and women in the criminal justice system often have high prevalence of traumatic events in their lifetime. James and Glaze (2006) reported that just over 25% of individuals with mental health issues in jails and prisons had histories of physical or sexual abuse. Wolf and Shi (2012) described that among males incarcerated in prison, rates of childhood physical, sexual, and emotional trauma were high (physical trauma in childhood alone was noted in 44.7% of the population), and that trauma exposure was strongly associated with behavioral and clinical difficulties. Subpopulations, such as female and military veteran offenders present with histories of unique and specific traumatic exposure, with concomitant additional challenges and needs (Saxon et al. 2001; Messina et al. 2014). Criminal justice involvement and incarceration can itself be traumatizing (Miller and Najavits 2012; Pinals and Andrade 2015). It is estimated that between 7% and 9% of community-based offenders who are under the supervision of probation and parole have histories of serious mental illness (Feucht and Gfroerer 2011), and they are at particular risk of re-arrest and re-incarceration.

The reasons for these high prevalence rates of individuals with mental illness with and without co-occurring substance use challenges in correctional populations are multifactorial. Although deinstitutionalization—the downsizing and closing of state psychiatric facilities—has been cited as a main causative factor, there are actually many complicated policy, legal, economic, and other factors that led to the current status (Pinals 2014).

Regardless of the causes, remedies are increasingly being emphasized that include behavioral health and justice system partnerships for innovation in collaborative services (Council of State Governments 2014). For example, efforts have been building to establish what in broad-based terms can be called "jail diversion." Although this is a term that is evolving and shifting to more nuanced approaches and definitions, the general theme for this umbrella term encompasses programs that are designed to divert and redirect individuals from the justice system to alternative treatment-based programs as a more appropriate and effective strategy for their care. This chapter will review the evolution of the concepts related to jail diversion and describe specialty programs that have developed to redirect individuals with mental illness and co-occurring disorders, when appropriate and safe, into alternative services.

FROM JAIL DIVERSION TO SEQUENTIAL INTERCEPT MODELS

Overview of jail diversion

Jail diversion is not a new concept. A review of this topic indicated that the concept of diversion had been a major advocacy position as early as the 1970s to help address the growing population and challenges faced by individuals with mental illness in jails and prisons (Steadman et al.

1994). In that same review, jail diversion was defined as formal and informal programs that screened detainees for mental disorders and used mental health professionals to evaluate those individuals who screened positive. This was followed by a negotiation with justice system professionals to yield a reduction in charges or a disposition outside of a jail setting instead of further prosecution. Further, the definition included programs that focused on a variety of strategies such as linkages to identified community services to reduce pretrial jail time (Steadman et al. 1994). In a large survey of a national sample of jail diversion programs in the mid-1990s, key factors in jail diversion were identified for program development, including (1) integrated services, (2) regular meetings with stakeholders, (3) boundary spanners across systems, (4) strong leadership, (5) early identification of individuals who would benefit from the program, and (6) distinctive case management-type services (Steadman et al. 1995). Though they were not the focus under review in these early descriptions, the authors noted that there were also programs related to pre-arrest jail diversion that operated with police and mental health partnerships.

In a more recent summary of 10 years of experience with jail diversion programing, it was noted that overall, jail diversion programs reduce time in jail and link individuals with mental health and co-occurring substance use disorders to community-based services, all without apparent increase in public safety risk (CMHS National GAINS Center 2007). According to this same review by the National GAINS Center, types of jail diversion that exist include pre-booking and post-booking diversion (see Table 26.1). Pre-booking diversion takes place generally at the point of contact with law enforcement. Post-booking diversion occurs following the arrest and includes the screening, evaluation, negotiation, and linkages for individuals to receive services in the community in lieu of incarceration. These post-booking diversion programs include specialty courts and nonspecialty court models that utilize either a deferred prosecution strategy or a strategy of placing special conditions on the individual through probation. The nonspecialty court models do not require regular court appearances if the individual is adherent with the provisions set out at the initial hearing. Jail-based diversion programs that are also part of the post-booking model can include those initiated by pretrial staff or specialized jail staff that help screen individuals and refer them to community-based services (CMHS National GAINS Center 2007).

Table 26.1 Examples of programs that redirect individuals with behavioral health disorders from deep end justice system involvement to treatment

1. Pre-booking
   a. Police crisis intervention teams
   b. Police and mental health crisis clinician co-response
2. Post-booking
   a. Pretrial diversion programs with local jails
   b. Deferred prosecution programs pre- or post-arraignment
   c. Specialty courts
      i. Drug courts
      ii. Mental health courts
      iii. Veterans treatment courts
      iv. Homelessness courts

Jail diversion programs thus incorporate many types of designs and services linking behavioral health with criminal justice. Over the last several years, in addition to focusing on individuals with mental illness, there has been increased emphasis on co-occurring substance use disorders and, given the high prevalence of trauma in the correctional population, recognition that all diversion strategies must take into account trauma-informed approaches (Osher and Steadman 2007). With jail diversion programs increasingly recognizing the complex interaction of one's trauma history and downstream sequelae, targeted interventions have been successfully developed that include screening for trauma and then building program models that address these factors.

Of note, although the definitions described above can be used in many jurisdictions, refined concepts of diversion occur in local jurisdictions. For example, from a pure criminal justice lens, some criminal justice professionals articulate that true diversion is only diversion if at the end of the effort, the criminal case is disposed of so there are no criminal charges on the individual's permanent record. Programs operating under this principle would necessarily be those that attach prior to the arraignment or the filing of the criminal complaint. By diverting an individual early, none of the collateral consequences (such as difficulties obtaining housing, specific employment, etc.) of a criminal record follow the individual. Given these nuances, it is important when working on collaborative models to ensure that the language and meaning of diversion is well-understood and accepted by all stakeholders in any particular jurisdiction. In this chapter, the word "diversion" is used to refer to the general meaning of those programs and services that help decrease jail days or deeper end involvement in the justice system for a targeted group of individuals with behavioral health disorders.

The initial logic behind diversion approaches was that if one could identify and enroll appropriate individuals with mental illness and link them to comprehensive and appropriate services in the community, there could be improved mental health outcomes, which would directly lead to improved public safety (CMHS National GAINS Center 2007). Over the years, research has increasingly demonstrated the need to focus on more than just mental health outcomes to enhance public safety, and as noted above programs increasingly target substance use disorders and other criminogenic risk factors that have been demonstrated as being more contributory to public safety outcomes and recidivism than mental illness (Osher et al. 2012).

For many of the diversion programs, the focus on reduced recidivism is accomplished through efforts that align with

the Risk–Need–Responsivity (RNR) model (Andrews and Bonta 2010). Because many people with mental illness commit crimes for the same reasons as people without mental illness (Fisher et al. 2014), the direct benefit of reduced recidivism from jail diversion programs seems most likely if the criminogenic factors are a focus of the intervention. Traditional clinical services have not embraced or incorporated these concepts yet. Although this model has been increasingly described relevant to jail diversion programs and seems promising, it has also been noted that there is more to learn and understand, and some caution needed, relative to its application to individuals with mental illness (Skeem et al. 2015). A more detailed discussion of the RNR framework is beyond the scope of this chapter but is noteworthy as this is an increasingly emphasized sorting approach to help determine who can benefit most from particular diversion strategies.

Introduction of the sequential intercept framework

As jail diversion programs have increased, collaborations and conversations between behavioral health systems and criminal justice systems have also become more common. An organizing framework to build these collaborations was described by Munetz and Griffin (2006) who conceptualized a public health-type framework that allowed for a parallel to primary, secondary, and tertiary prevention of further penetration of individuals with mental illness in the justice system. Specifically, they described what is known at the Sequential Intercept Model (SIM; see Figure 26.1). This framework depicts the criminal justice system along a continuum and describes how it can offer several potential points of interception at which individuals with serious mental illness could be identified and then linked to community services in lieu of incarceration.

Since its initial description, the SIM model has helped many jurisdictions build services in a fashion that is organized around these intercept points. Recently, SIM workshops have also become more common (Policy Research Associates 2014). The framework has been used also to focus on specific populations beyond those with serious mental illness. For example, certain veterans' services have been examined to ensure appropriate linkages for justice involved veterans across the criminal justice intercepts (Blue-Howells et al. 2013). Similar frameworks pointing out areas for intervention have been promoted to help redirect youth with mental health challenges into treatment services from the juvenile justice system (Skowyra and Cocozza 2006). The National GAINS Center, funded through the Substance Abuse and Mental Health Services Administration (referenced noted above), has promoted a pictorial representation of the SIM upon which behavioral health and other systems can map their services, and allow for further conversation related to gaps and needs. By fostering collaborative discussion, systems can enhance diversion strategies of all types across all points of the justice system. Next we turn to examine diversion strategies at specific intercept points.

POLICE-BASED DIVERSION

If one looks at the criminal justice system as a funnel, the most robust impact for diversion could be considered at the level of law enforcement. Fisher and colleagues examined data regarding consumers of state mental health services over 10 years and found that 28% had experienced at least one arrest (Fisher et al. 2006). Deane and colleagues (1999) found that about 7% of police contacts across numerous police departments and cities involved an individual with mental illness. For decades there has been the recognition that police play a critical role in decisions to arrest or to potentially help individuals with mental illness (Liberman 1969; Lamb et al. 2002) by directing them to treatment. Because of the high prevalence of arrest among individuals with mental illness, these decision points are critical. The degree of discretion an officer has with regard to the outcome of a particular encounter can vary greatly, and officers are often faced with choices with regard to what type of disposition may follow. Teplin and Pruett (1992) described the police as "streetcorner psychiatrists" and noted that there were numerous variables that contributed to officer decisions regarding the handling of particular encounters with individuals with mental illness. A more recent study out of Australia found that the severity of presenting symptoms and the officer's attitudes toward people with mental illness were most highly related to how officers would likely respond to a series of vignettes (Godfredson et al. 2010). Another study found that neighborhood factors were associated with decisions of police to refer individuals to services (Krishan et al. 2014).

Police-based diversion strategies have emerged as critical to decreasing the front door to the criminal justice system

when appropriate and safe. In some cases, these programs have been developed after highly publicized incidents of fatal shootings of an individual with mental illness by law enforcement. Others have evolved by interest in avoiding such circumstances or by the growing interest in developing community solutions to the challenges faced when persons with mental illness may have difficulty or reluctance in accessing services and then engage in behaviors that come to the attention of the police.

There are several main strategies related to law enforcement or pre-arrest diversion, which can be categorized based on the primary agency responsible for the response and based on the type of professional primarily responding to the situation (Borum 2000; Pinals and Price 2010). A police-based specialized police response involves a specially trained police officer who has specific knowledge regarding mental illness and mental health resources who responds to a scene. In a police-based specialized mental health response, there are mental health clinicians who are stationed within the police department to accompany the police for calls involving "emotionally disturbed persons" and to assist with follow-up visits and other activities. These events, when a clinician goes to a scene with the police, are often called "ride-alongs" or "co-responder" models. Finally, a mental health-based specialized mental health response includes services also known as mobile crisis services. These programs are generally funded through community-based mental health centers, Departments of Mental Health, or through providers that serve mental health needs of a region. These programs become familiar with the regional resources and often develop formal partnerships and memorandums of agreement with local police, so that they can develop the capacity for joint responses to specific crisis calls.

One of the critical areas in police-directed diversion is in providing officers with the training needed to best respond to situations involving individuals with mental illness. Crisis Intervention Team (CIT) training involves a 40-hour curriculum for a proportion of officers within a police department, who then become part of a specialized response team that can provide for improved recognition of the signs and symptoms of mental illness and the transition of individuals to treatment services instead of arrest. This model was developed in Memphis after a tragic incident involving a police officer's use of lethal force toward an individual who had mental illness. The goals of the program involve the training but also emphasize development of linkages to drop-off sites for immediate treatment access, as well as policies and procedures to better manage individuals in crisis and develop collaborations between police and treatment service agencies. The curriculum is broad and includes areas such as an overview of mental illness, direct lectures by persons with mental health challenges in recovery and tours to their living facilities, as well as training on de-escalation techniques (Schwarzfeld et al. 2008).

Studies of CIT have demonstrated its advantages in terms of decreased injuries to officers (Dupont and Cochran 2000; Reuland et al. 2009). Findings demonstrate the effectiveness in CIT officers making referrals to community services in lieu of arrest (Reuland et al. 2009; Compton et al. 2014). Hundreds of communities have initiated CIT development, and interest in the model continues to grow exponentially (Compton et al. 2008).

As noted, the model of specialized mental health response that partners with police is often referred to as the co-responder model. It was first formally developed as a way to enhance linkages of individuals with mental illness to appropriate services. The model evolved to include building pairs of specially trained officers who jointly responded to community crisis scenes with specialized mental health professionals (Reuland et al. 2009). Jurisdictions that utilize this model have shown success in diverting individuals who otherwise may have been arrested. Data from Massachusetts programs that have included both CIT and co-responder programs, for example, show a number of types of criminal charges that were averted or delayed to allow the individual to receive treatment intervention (Orr and Pinals 2014).

Lamb and colleagues (2002) articulated the value of police and mental health partnerships but also spoke of the importance of clarifying roles and responsibilities of mental health professionals and law enforcement as police responses were beginning to be examined. The Council of State Governments Justice Center, in partnership with the Police Executive Research Forum, carved out 10 essential elements to improving police responses for people with mental illness (Schwarzfeld et al. 2008). The elements range from collaborative planning and implementation, specialized training, and protocols related to information exchange, custodial transfer, disposition planning, and program evaluation, to name a few (Schwarzfeld et al. 2008). This type of roadmap has assisted with community development of these models. Several states now have such police diversion programs statewide (Reuland et al. 2012).

Although CIT and other pre-booking models of diversion were developed in large part to better redirect individuals with serious mental illness, additional focus has been on other populations. For example, CIT training most typically now includes training related to veterans and the trauma-informed approaches to utilize. In addition, a youth version of CIT, called CIT-Y, has also been promoted, and this can encompass training for school resource officers and line police, as well as partnerships with police, schools, and child-serving agencies, given the prevalence of arrests that seem to take place on school grounds, and the high proportion of youth with behavioral health conditions in the juvenile justice system (National Alliance on Mental Illness 2014; see also the National Center on Mental Health and Juvenile Justice at http://www.ncmhjj.com/). Additionally, police-based diversion programs are being built that also serve individuals with significant substance use issues, again in an effort to avoid arrest if treatment is needed and reasonable. At times, when the manifest behavior allows for police discretion, frustration with wait times

in emergency rooms or a limited likelihood of retaining the patient in treatment can result in decisions to take someone into custody. Because of this, communities are also building alternatives that allow police options that maximize their efficiency as well as maximize the likelihood of the individual accessing treatment as soon as possible. For example, the San Antonio "Restoration Center" was created as an additional response to overcrowding in the local jail and the high prevalence of individuals with mental illness and co-occurring disorders among the population (National Public Radio 2014).

As more locales tackle better responses to individuals in the community who present with behavioral health crises, and more people are potentially diverted from arrest, it is important to address any service gaps to avoid repeated cycling. Creative collaborative models therefore catalyze community innovations making diversion programs meaningful to address the original goals of redirecting people away from the justice system and into treatment. Significant savings were reported related to the Restoration Center, both from the jail costs and from police overtime costs. More information over time will undoubtedly emerge about these types of cooperative diversion programs as community partnerships strengthen.

SPECIALTY COURTS AND OTHER COURT-BASED MODELS

Court-based interventions designed to decrease the jail usage and deeper end criminal justice involvement for individuals with mental illness and co-occurring disorders range in type as noted above. One such intervention is through what is referred to as "specialty courts." These consist of devoted court sessions where individuals, either pre-trial or post-adjudication, and as part of court-ordered probation, return to face the judge on a regular basis and work with others to help achieve better outcomes. Agreement to participate in a specialty court is generally done as a way to avert a jail sentence and minimize jail days.

In 1989, the first drug court was established in Miami–Dade County, Florida, and drug courts have increased in number ever since, currently numbering over 2700 across the country (National Association of Drug Court Professionals [NADCP] 2014). Drug courts operate on the model of therapeutic jurisprudence for a participant, who agrees to the terms of the drug court in lieu of incarceration. The "treatment" is delivered through the development of a drug court "team," most often consisting of treatment providers, probation, other courtroom personnel, and led by the presiding justice. Together the team members determine eligibility for drug court participation and then track progress through a series of advancing phases marked by sobriety and enhanced prosocial community engagement. Higher-risk offenders are generally the target population. Treatment phase advances are achieved by the rigorous use of sanctions (including anything from verbal admonishment up to and including brief periods of incarceration) and rewards (including anything from verbal praise to less frequent required appearances in court), leveraging the authority of the presiding judge and the overarching criminal case. There are key components of drug courts that are promulgated by the National Association of Drug Court Professionals (NADCP 2004). These components include a coordinated strategy that governs drug court responses to participant compliance, a nonadversarial approach whereby the participant's due process rights are protected and prosecution and defense promote public safety, as well as monitoring and evaluation to measure effectiveness.

Initial work related to drug court findings was largely anecdotal and qualitative but showed terrific promise, and organizations such as the NADCP and the National Drug Court Institute were born. Rigorous empirical drug court literature is still being produced, which is critically important but complex, especially given the methodological challenges in this body of research, where individual drug courts may vary in significant ways. One review of numerous studies across drug courts found that although arrests of participants may not have decreased, there was an overall reduction in re-conviction and re-incarceration for drug court participants across studies (Brown 2010). More recently, Larsen and colleagues demonstrated that there may be a way to more effectively assist drug court participants as we refine our understanding of subpopulations that may warrant specific interventions (Larsen et al. 2014).

Adult drug courts inspired a series of other specialty court programs, including mental health courts (discussed further below), juvenile drug courts (Henggeler 2007), veterans treatment courts (Pinals 2010), reentry courts, homelessness courts, and others. For each of these interventions, a target population or issue is identified, and the resources needed to assist this individual and to reduce the cycling through the justice system become targeted goals. For example, in a Veterans Treatment Court, on the day of the session, the courtroom is donned with military flags and will have among the observers representatives from veterans service agencies and formal veteran peer supports who stand ready to assist the veterans, screen referrals, and link the veterans to treatment services. Key components for these veterans treatment courts are also developed and promulgated, in large part through the NADCP.

As these models grow, there is recognition of the need to examine the challenges faced by the participants through a lens that encompasses attention to co-occurring substance use, mental health disorders, and trauma histories (Osher and Steadman 2007). For example, Steadman and colleagues helped articulate six steps to improve drug court outcomes for individuals with co-occurring mental health and substance use challenges (Steadman et al. 2013). The steps included understanding the needs of the drug court participants, adapting court structure according to the needs of participants, expanding treatment options to include mental health treatments, building in targeted case management and supervision, and expanding models for collaboration.

There are now hundreds of mental health courts in existence in the United States. These programs developed as another approach to the specialty court movement. These court sessions are viewed as targeting a wide range of individuals with a variety of mental health challenges. The Council of State Governments has produced a series of primers to help direct the field in the development of these programs. Following the theme of key guidelines, in one of their publications (Thompson et al. 2007) they provide the "Essential Elements" of a mental health court, including (1) planning and administration, (2) target population, (3) timely participant identification and linkage to services, (4) terms of participation, (5) informed choice, (6) treatment supports and services, (7) confidentiality, (8) court team, (9) monitoring adherence to court requirements, and (10) sustainability.

Recent literature on mental health courts reported their effectiveness in reducing jail days and increasing participation in community treatments and improved outcomes (Steadman et al. 2011; Goodale et al. 2013). The mental health court research has also examined a variety of nuanced issues about these programs. Studies have shown that programs can be effective even when they take in individuals who were charged with higher-level offenses (Reich et al. 2012), because early mental health courts focused on low-level offenses, though the RNR framework has not generally been the starting place for eligibility for mental health courts. Eligibility seems to rely on a selection process that uses formal and informal criteria, and is influenced by local available mental health services (Wolff et al. 2011). In this way, treatment planning is also somewhat more individualized than is seen in drug courts. In addition, perceived voluntariness and procedural justice were associated with greater program success, that participants receive more community-based mental health services but perhaps insufficient services to address criminal risk factors (Luskin 2013). Also, although participants do well in these types of diversion programs, there may be a high prevalence of them who are incompetent to stand trial, and this issue, along with competence to consent to treatment, likely warrants further attention (Stafford and Wygant 2005). With the growth of mental health courts as community-based alternatives to jails and other institutional settings, cost factors for their success will need to be examined. These programs have been thought of as opportunities for cost savings to the criminal justice system, and it is hoped that with greater stability there would be additional cost savings related to treatment services. However, one recent study showed that there may be additional treatment-related costs associated with them that will require further examination of how best to maximize their effectiveness and efficiencies (Steadman et al. 2014). Overall, however, specialty courts offer one important national approach to alternatives to incarceration that are meant to preserve individual rights and still protect public safety while providing a better service to society.

Additional court-initiated programs that do not require regular appearances in front of a judge can also be considered to fall under the array of "diversion" strategies. In particular, Osher and colleagues describe innovations working with the large number of individuals under community-based correctional supervision (Osher et al. 2012). These approaches include a framework for addressing a multitude of areas of need simultaneously by determining criminogenic needs, followed by ascertaining the level of substance use and mental health needs, and developing treatment programs that can address all three. Using this approach and embedding the RNR framework for planning for services could potentially then better achieve the reduction in recidivism as an outcome variable. One such model that is currently being applied to a variety of diversion services including probation-based court-mandated community services is MISSION-Criminal Justice (see Missionmodel.org; Pinals et al. 2014; Smelson et al. 2014), which incorporates several evidence-based practices using a peer and case management team to provide manualized community-based support and linkage interventions for those individuals with co-occurring disorders who are in the criminal justice system. Such models highlight the importance of decreased criminal recidivism as part of an overall holistic recovery strategy. Other models, such as the Veterans Administration-funded Veterans Justice Outreach program, is an attempt to offer support services for court-involved veterans who may be able to be diverted from jail with such support (Pinals 2010). Peer support services are also attached to specialty courts and other diversion programs.

REENTRY AND COMMUNITY-BASED JUSTICE–BEHAVIORAL HEALTH SERVICES

The transition from incarceration to community living is a period of tremendous stress and uncertainty. Although not considered jail diversion in the purest sense of the term, reentry programming and community-based interventions upon reentry aimed to keep individuals with mental illness and co-occurring substance use disorders from being re-arrested and returning to incarceration are viewed as important prevention strategies. In addition to the risk of re-arrest, morbidity and mortality for individuals with co-occurring disorders coming out of prisons is high (Binswanger et al. 2007). These factors taken together have contributed to a growing trend toward enhanced reentry services.

Over a decade ago, the APIC (Assess, Plan, Identify, Coordinate) model for reentry was asserted as a best practice model for inmates with these types of behavioral health challenges (Osher et al. 2002). This model encompasses necessary components for linking individuals to the right services upon custodial release. A period of in-reach and post-incarceration follow-up appears helpful in smoothing this transition for the individual. Specific service delivery models, such as Critical Time Intervention, a case management model that decreases in intensity over a period of increased stability and acceptance of the transition, has shown positive effects with reentry work with individuals

with serious mental illness (Draine and Herman 2007). Community-based multidisciplinary treatment programs, such as Forensic Assertive Community Treatment, have shown a positive effect in decreasing revolving-door trends for individuals with serious mental illness who cycle through the criminal justice system (Lamberti et al. 2004; Cuddeback et al. 2008; Angell et al. 2014). MISSION-Criminal Justice, described above, has been used successfully in reentry services for male and female offenders with co-occurring disorders and trauma histories, and further studies of this are underway. Taken together, these types of programs and efforts recognize the importance of adding re-entry services and community-based behavioral health–criminal justice collaborations as part of the framework of strategies to decrease the criminalization of the participants.

SUMMARY

Police-based pre-booking jail diversion, specialty courts, and reentry services all have the goal of decreasing the involvement of individuals with mental illness and co-occurring substance use disorders in the criminal justice system and redirecting them to treatment. These efforts will undoubtedly continue to grow, and federal funding is rapidly attempting to push innovations to communities to establish enhanced behavioral health and criminal justice collaborative efforts. With these trends, the phenomenon of "decarceration" is likely to create shifts in where these individuals, especially those with criminogenic characteristics, are served. These trends will further inspire the need to have specialized programs available to assist the individuals who have benefitted from them (Lamb and Weinberger 2014). From a risk assessment and risk management perspective, these collaborative programs hold promise as individuals with criminal histories and possible violence history are released and in need of support. Forensic psychiatrists should be familiar with these opportunities to intervene, as they will likely be increasingly providing forensic assessments and treatment as part of these partnerships with criminal justice programs.

SUMMARY KEY POINTS

- Jail diversion can be construed as an umbrella term that encompasses a variety of programs designed to reduce jail days, defer prosecution, and link individuals with mental illness and co-occurring substance use disorders into treatment services.
- Police diversion strategies have shown promise in re-directing individuals to treatment prior to a criminal complaint moving forward.
- Specialty courts include a target population and regular appearances in front of a judge, as well as an array of staff that become part of the specialty court team to address and help reduce recidivism.
- As emerging models of police diversion, specialty courts, and reentry services develop, further research will be needed to understand their effectiveness, as well as cost factors that can inform policy planning.

Criminal competencies

STEPHEN G. NOFFSINGER AND PHILLIP J. RESNICK

INTRODUCTION

An arrest sets in motion the events of criminal prosecution: booking, arraignment, discovery, plea negotiations, trial, sentencing (if convicted), and possible appeal. The recent arrest rate in the United States was 3888 arrests/100,000 persons, resulting in more than 12,000,000 arrests annually (Federal Bureau of Investigation 2012).

Mentally ill defendants are overrepresented in the criminal justice system (Skeem et al. 2011, 110), because they have a significantly greater chance of arrest (Teplin 1984, 800). Therefore, a substantial number of mentally disordered individuals are prosecuted through the criminal justice system in the United States. Mental disorders potentially impact defendants' ability to competently defend themselves from prosecution. Accordingly, forensic psychiatrists are frequently requested to evaluate criminal defendants' competence to participate in one or more phases of criminal prosecution.

CONCEPT OF COMPETENCE

Competence generally involves the ability to understand a body of knowledge and rationally apply that knowledge to a decision-making process. Competence refers to a mental state at a specific point in time. Mental illness can fluctuate over time; therefore, competence may also vary over time. Evaluating competence may be a present-state (e.g., competence for medical decisions) or a retrospective evaluation (e.g., competence to execute a will on a past date).

Assessing most criminal competencies involves evaluating the defendant's present mental state. Infrequently, a defendant's competence to stand trial, confess, plead guilty, or waive counsel is the basis of a post-conviction appeal—in these circumstances the evaluator retrospectively assesses the defendant's mental state and competence (*U.S. v. Bergmann* 2010; Kapalczynski and Noffsinger 2011, 581).

A mental disorder does not automatically indicate incompetence. Even a severely mentally disordered individual may be competent if his or her symptoms do not impair the mental functioning required for competence. However, a single delusion may render a well-appearing individual incompetent. An otherwise competent defendant with the single delusion that his or her attorney is demonic may be incompetent to stand trial, because the defendant's delusion may cause him or her to irrationally resist cooperating with the attorney.

Prior to the 1960s the concept of global incompetence was embraced—a person adjudicated incompetent in one area was deemed incompetent in all areas (Appelbaum and Gutheil 2007, 227). Many state laws indicated that civilly committed patients, based on their status as an involuntarily hospitalized patient, were incompetent to make decisions about their financial affairs, treatment, voting, and marrying. Beginning in the 1950s–1960s, courts, clinicians, and legislators realized that mental disorders may *selectively* impair functioning. With that realization the concept of specific competencies evolved, and more than 30 types of competence are now defined in law. Hence, an adjudication of incompetence in one area no longer means incompetence in other areas.

COMPETENCE TO STAND TRIAL

Criminal defendants have the right to be tried only if competent to stand trial (*Pate v. Robinson* 1966). Trying only competent defendants safeguards the accuracy of adjudication, ensures the fairness of the adversarial process, maintains the dignity of the court, and, if convicted, guarantees that the defendant knows why he or she is being punished (Ausness 1978, 666; Barnard et al. 1991, 367). Trials are more reliable when the defendant is competent (Bonnie 1990, 427). Fairness demands that the defendant know what is happening during the trial and contribute to his or her defense, and the dignity of the law is protected when a convicted defendant knows why he or she is being punished (Buchanan 2006, 458).

The U.S. Constitution guarantees defendants facing trial specific rights, including the Sixth Amendment's right to assistance of counsel and right to confront witnesses, and the Fourteenth Amendment's rights to substantive and

procedural due process of law. Mental illness may impact a defendant's ability to exercise these rights. Mentally disordered defendants may be unable to cooperate with counsel and/or confront adversarial witnesses, effectively denying Sixth Amendment rights. Trying an incompetent defendant is fundamentally unfair, in violation of the substantive due process clause of the Fourteenth Amendment. Mentally disordered defendants may not be able to understand and exercise Fourteenth Amendment procedural due process rights.

History of competence to stand trial

The common law doctrine that defendants must be mentally competent to stand trial has been part of the criminal law for centuries (Ausness 1978, 666). The concept of trial competence began in thirteenth-century trials before the king's court in England. Defendants who failed to enter a plea were given three warnings by the court, and then confined and starved (*prison forte et dure*) or gradually crushed under increasing weights (*peine forte et dure*) (Statute of Westminster 1275) until they entered a plea or died (Grubin 1996). The phrase "to press someone for an answer" originated here. Before engaging such methods, the king's court investigated whether the defendant was intentionally withholding a plea (mute by malice), or whether, due to a mental defect, was unable to understand that a plea was required of him or her (mute by visitation of God). Defendants mute by visitation of God were spared the methods described above and a not guilty plea was entered for them. The difficulty in trying an incompetent defendant was recognized by courts as early as 1353 (Walker 1968, 219).

Legal standards for trial competence developed during subsequent centuries. In the Somervile trial (1583), the defendant was thought to be incompetent only if "absolutely mad." The Dyle trial (1756) specified a defendant's incompetence "if not of sound mind or memory." The most detailed early nineteenth-century competence standard came from Pritchard's trial (1836) that required that "the prisoner has sufficient understanding to comprehend the nature of the trial, so as to make a proper defence to the charge…sufficient intellect to comprehend the course of proceedings at trial, so as to make a proper defence—to know that he might challenge any of you to whom he may object—and to comprehend the details of the evidence."

Competence to stand trial standards

The U.S. Supreme Court articulated American trial competence standards in *Dusky v. United States* (1960), which inquires "whether the defendant has sufficient present ability to consult with his lawyer with a reasonable degree of rational understanding—and whether he has a rational as well as factual understanding of the proceedings against him." While *Dusky* did not require that mental illness be the basis for incompetence, the subsequently adopted federal Insanity Defense Reform Act (1984) required a present mental disease/defect as the cause of incompetence.

American states adopted trial competence standards similar to the *Dusky* standard. State and federal standards indicate that defendants are incompetent to stand trial if their mental illness makes them (1) unable to understand the nature and objectives of the proceedings and/or (2) unable to assist in their defense.

Evaluating competence to stand trial

Trying an incompetent defendant risks erroneous conviction; therefore, defense attorneys often request evaluation of their client's trial competence. Prosecutors and judges are also concerned about the mentally disordered defendant's trial competence. Trying an incompetent defendant may lead to an appeal of any conviction, and justice is not served by trying an incompetent defendant.

Defense attorneys question their client's trial competency in 8%–15% of felony prosecutions (Hoge et al. 1992, 389; Poythress et al. 1994, 439). Evaluations are sought due to a history of mental illness; behavior suggesting a mental disorder (currently or during the offense); and/or an uncooperative or irrational client (*Drope v. Missouri* 1975). The defense most often requests for a competence assessment, triggering the court to order the evaluation.

Competence to stand trial evaluations are among the most common court-ordered evaluations—approximately 60,000 are performed annually in America (Mossman et al. 2007, S3). Most are performed as an outpatient, although an inpatient evaluation may be arranged for the defendant who is uncooperative or suspected of malingering (Grisso et al. 1994; Soliman and Resnick 2010, 624). Approximately 20%–30% of defendants evaluated for trial competency are opined incompetent to stand trial (Cooper and Zapf 2003, 429).

The competence evaluation methodology includes the following:

1. Reviewing the defendant's relevant medical records.
2. Reviewing relevant collateral sources of information (school records, interview family members, etc.).
3. Personally interviewing the defendant, including:
   a. A psychiatric diagnostic interview and mental status examination. The defendant's orientation, memory, concentration, mood, affect and the presence of delusions, hallucinations and loose associations are especially relevant.
   b. Inquiring into the specific areas of competency to stand trial (see below).
4. Providing a written report with a well-reasoned opinion by applying the facts of the case to the competence standard in the relevant jurisdiction.

Most jurisdictions prohibit information obtained during a competence evaluation from being used to prove a defendant's guilt (e.g., O.R.C. 2945.371J). The defendant's confession made during a competency evaluation is inadmissible at trial.

The question sometimes arises as to whether the defendant is competent to consent to a competence to stand trial assessment. In the event that the examiner suspects that defendant lacks capacity to give informed consent for the competence evaluation, the evaluator should nevertheless proceed with the evaluation. The examiner is acting pursuant to a court order, and practically speaking, the court must be informed of the defendant's likely incompetence.

Specific inquiries are made during a competence to stand trial evaluation. The following areas should be examined (Resnick and Noffsinger 2004, 333):

1. Ability to Understand Nature and Objectives of Proceedings:
   a. Charges—The defendant must be able to understand the charges and the nature of the conduct alleged.
   b. Role as defendant—Defendants should be able to understand that they are charged with a crime and are facing prosecution (Bonnie et al. 1997, 250). A defendant delusionally believing that he is immune from prosecution is likely incompetent.
   c. Severity of charge—A defendant should be able to understand the severity of the charge and the possible range of penalties.
   d. Pleas—A defendant should be able to understand the pleas of Guilty, Not Guilty, No Contest, and Not Guilty by Reason of Insanity (and Alford pleas and Guilty but Mentally Ill, in some jurisdictions).
   e. Courtroom personnel roles—A defendant should be able to understand the roles of the defendant, defense attorney, judge, prosecutor, jury, witness, and victim.
   f. Adversarial nature of trial—A defendant should be able to understand which court personnel are acting adversely to their interests and demonstrate self-protective behavior.
2. Ability to Assist in Defense:
   a. Cooperate with defense attorney—A defendant must be able to have rational discussions and communicate relevant information to his or her defense attorney, and be free of paranoid ideas about the attorney. An incoherent or mute defendant is likely to be incompetent (Bonnie et al. 1997, 250).
   b. Understand plea bargaining—Approximately 85% of defendants plea bargain—pleading guilty in exchange for reduced charges, reduced sentence, or both. Defendants must understand the concept of plea bargaining and be able to rationally make decisions about plea bargaining.
   c. Willingness to consider mental-disorder defense—A defendant must possess sufficient insight into his or her illness to consider pleading Not Guilty by Reason of Insanity (Reisner et al. 2013, 88), Guilty but Mentally Ill, or seeking mitigation due to mental illness, if relevant. Otherwise competent defendants who irrationally refuse a mental-disorder defense may have such a defense imposed on them by the court and proceed to trial (*Frendak v. United States* 1979).
   d. Appraisal of evidence and estimate of likely outcome of trial—A defendant should be able to determine which evidence is helpful/harmful to the case; reasonably estimate the chances of conviction; and apply this information in deciding whether to accept a plea bargain.
   e. Attention, memory and concentration—A defendant should be able to pay attention during trial, and have sufficient memory to retain and apply the information during trial.
   f. Understand appropriate courtroom behavior—A defendant should be able to understand and exercise appropriate courtroom demeanor. It is important to differentiate between a defendant who (due to illness) is incapable of acting appropriately from a defendant who elects to act inappropriately.
   g. Rational account of offense—A defendant should be able to give a consistent and organized account of the offense. Such an account may help to achieve alibi, acquittal, insanity, or mitigation. However, a defendant with permanent amnesia for the offense is not categorically incompetent to stand trial (*Wilson v. United States* 1968).
   h. Formulate defense plan—A defendant should be able to work with his or her attorney to develop a basic plan of defense, working toward the goal of acquittal or mitigation.
   i. Make reasonable defense decisions—Using his or her knowledge of the information listed above, a defendant should be able to rationally apply that knowledge to his or her defense and make reasonable, logic-driven decisions (Morris et al. 2004, 243; Felthous 2011, 27).
   j. Freedom from self-defeating behavior—A defendant should be motivated to seek the best possible outcome for his or her trial. Defendants who seek an unfavorable outcome, due to mental illness, may be incompetent to stand trial.
   k. Testify at trial—A defendant should be able to give rational, organized, and logical trial testimony that may assist in his or her defense. A defendant should also be able to withstand the stress of testifying and being subject to cross-examination.

Competence to stand trial structured assessment instruments

Many structured instruments have been developed to assess trial competence: the Competency Screening Test (Lipsitt et al. 1971); Competency to Stand Trial Assessment Instrument (U.S. Department of Health 1973); Interdisciplinary Fitness Interview (Golding et al. 1984); Competence Assessment for Standing Trial for Defendants with Mental Retardation—CAST*MR (Everington 1990); and Georgia Court Competency Test (Nicholson et al.

1988). Some instruments are of limited utility, as they assess a defendant's factual understanding, but not reasoning ability (Hoge et al. 1997, 144). In recent years, additional competence assessment tools have been introduced, including the Computer-Assisted Determination of Competency to Stand Trial (CADCOMP) (Barnard et al. 1991); Evaluation of Competency to Stand Trial-Revised (ECST-R) (Rogers et al. 2004); and Inventory of Legal Knowledge (ILK) (Otto et al. 2011). Canadian researchers have developed the Fitness Interview test to address the Canadian competency standard (Zapf et al. 2001, 426).

The MacArthur Competence Assessment Tool—Criminal Adjudication (Mac-CAT-CA) assesses "adjudicative competence" that includes competence to enter a plea, stand trial, and participate in pretrial proceedings (Hoge et al. 1997). The Mac-CAT-CA assesses factual knowledge and decisional competence.

Structured competency assessment instruments are not diagnostic tests that decide whether a defendant is competent to stand trial. Rather, the instruments' designers recommend that clinicians consider test results as one source of information, interpreting those results in light of the clinical interview and other relevant data (Mossman et al. 2007, S43). The recent trend has been for examiners to increasingly utilize standardized assessments as one source of data when conducting competence evaluations (Rogers and Johansson-Love 2009, 459).

Outcome of competence evaluation

Competence to stand trial is addressed by the court in a competency hearing (*Pate v. Robinson* 1966; *Drope v. Missouri* 1975) and is a legal question adjudicated by a judge. There is a presumption of competence to stand trial. Preponderance of the evidence is the standard of proof required to prove incompetence (*Cooper v. Oklahoma* 1996). An incompetent defendant may not be convicted (*Pate v. Robinson* 1966). Clinical competency opinions are admitted into evidence at a competency hearing. Courts usually (up to 90%) base the adjudication of competence on the opinion of the court-appointed clinician (Reich and Tookey 1986; Freckelton 1996).

Most defendants examined for competence to stand trial are opined competent (Cooper and Zapf 2003, 429). A mental disorder is insufficient to conclude that a defendant is incompetent. In one study, almost one-third of defendants opined competent to stand trial had a psychotic disorder (Roesch et al. 1981, 151). In addition to a mental disorder, incompetence requires that the mental disorder impair the defendant's performance in the specific functional areas relevant to competence. Examiner decisions of competence appear to be unbiased and relate primarily to a defendant's functional ability (Cooper and Zapf 2003, 423).

Approximately 20%–30% of defendants evaluated for competence to stand trial are adjudicated incompetent (Nicholson and Kugler 1991; Cooper and Zapf 2003, 429; Pirelli et al. 2011, 13), although there is a wide range (4%–77%) of incompetency rates in different jurisdictions (Cochrane et al. 2001). Approximately 37%–50% of geriatric defendants are found incompetent (Heinik et al. 1994; Frierson et al. 2002). Males and females are equally likely to be found incompetent (Riley 1998, 229).

Younger adults are likely incompetent due to psychosis, mood disorder, or intellectual disability, while older defendants are likely incompetent due to dementia (Frierson et al. 2002). Positive psychotic symptoms, particularly conceptual disorganization and delusional thinking, are significantly associated with incompetence (James, 2001, 139; Lee et al. 2014, 1010). Preteens and young adolescents are frequently incompetent due to their inability to disclose relevant data to counsel, susceptibility to outside influence, inability to appraise the quality of legal representation, and difficulty making defense decisions (McKee 1998; Slovenko 2000).

Severity of the charge has little effect on incompetency rates, although recent authors suggest that complicated legal cases require a larger degree of mental capacity. Therefore, the competence required to stand trial on serious charges should be greater than for minor charges (Buchanan 2006, 459; Buchanan 2008, 352).

Feigning incompetence to stand trial is a legitimate concern. Defendants facing possible conviction may have a motive to avoid trial. Estimates of feigned incompetence range from 8% to 21% (Soliman and Resnick 2010, 614).

Clinicians opining that a defendant is incompetent to stand trial must make a prediction whether the defendant is likely to be restored to competence, given treatment. The U.S. Supreme Court ruled in *Jackson v. Indiana* (1972) that a defendant cannot be held for more than the reasonable period of time necessary to determine whether there is substantial probability that he or she will attain competency in the future.

Defendants adjudicated incompetent to stand trial are usually committed to a hospital for competency restoration treatment. Approximately 7000–9000 defendants are involuntarily committed to public hospitals annually for competency restoration (Steadman and Hartstone 1983; Davis, 1985), although that number is likely much higher in recent years. A growing number of incompetent defendants are unable to access needed mental health care because of shortages in state hospital psychiatric beds (Wortzel et al. 2007, 357).

Approximately 66%–90% of defendants referred for competency restoration are successfully restored to competency (Noffsinger 2001; Morris and DeYoung 2014, 87). Competency restoration rates vary, depending on illness severity and time allowed for competency restoration. Restoration to competence is accomplished by treating the defendant's mental illness and providing education about the trial process (Noffsinger 2001; Wall et al. 2003, 195). (See Chapter 28.)

Incompetent defendants who incompetently refuse antipsychotic medication may receive involuntary treatment to restore trial competency. The involuntary treatment must be the least intrusive treatment for restoration of competence

and must be medically appropriate (*Riggins v. Nevada* 1992). A defendant adjudicated incompetent to stand trial who nevertheless competently refuses antipsychotic medication may still receive involuntary treatment, if the prosecution can prove that there is a compelling governmental interest at stake, such as bringing a defendant to trial on major charges (*Sell v. United States* 2003).

For defendants who cannot be restored to trial competency, charges are dismissed or held in abeyance. Common reasons for unrestorability include treatment-resistant psychosis, dementia, and moderate to severe intellectual disability. Factors associated with unrestorability include impairment in psycholegal ability and presence of severe psychotic symptoms (Advokat et al. 2012, 90). Characteristics of unrestorable defendants include more prior hospitalizations, more prior incarcerations, more previous findings of incompetence, lower-level charges, psychotic disorder, cognitive disorder, more medications prescribed, and lower global assessment of functioning scores (Colwell and Gianesini 2011, 297, Rotter and Greenspan 2011, 307). Unrestorable defendants may remain hospitalized only if civilly committed (*Jackson v. Indiana* 1972).

COMPETENCE TO WAIVE EXTRADITION

Defendants may be arrested in a jurisdiction different from where their charges originated and where they will be tried. Defendants can challenge extradition (transfer) to a requesting state. Only a handful of states have explicitly considered the issue of a defendant's right to be competent to proceed with an extradition hearing. In some states, competence to participate in an extradition hearing is similar to competence to stand trial, in that the defendant must understand factual material related to extradition under the Uniform Criminal Extradition Act and be able to assist defense counsel at the extradition hearing. Some states apply a more limited competency standard related solely to particular requirements of extradition (as to identity and fugitive status). Finally, a limited number of states have found that a fugitive has no right to be competent to proceed in an extradition hearing.

COMPETENCE TO CONFESS

The privilege against self-incrimination indicates that a defendant cannot be compelled to testify against himself or herself. The U.S. Supreme Court ruled in *Miranda v. Arizona* (1966) that the Fifth Amendment requires that police inform custodial defendants of their rights to remain silent; to counsel; and that any statements the defendant makes can be used against them. Defendants may waive *Miranda* rights and give a confession that may be introduced at trial by the prosecution as evidence of guilt. The standard for competence to waive one's *Miranda* rights (or any Constitutional right) is whether the defendant knowingly, intelligently (*Johnson v. Zerbst 1938*), and voluntarily waived that right.

With respect to the voluntariness of waiving *Miranda* rights, the U.S. Supreme Court ruled in *Colorado v. Connelly* (1986) that *police coercion* is necessary for a court to find that a defendant's confession was incompetently made. Evaluating the behavior of law enforcement officers to determine if police coercion occurred is usually beyond the expertise of the forensic mental health professional; however, the clinician may be asked to retrospectively evaluate the defendant's mental state during the confession and susceptibility to potentially coercive police behavior.

In addition, clinicians may retrospectively evaluate whether a defendant competently waived *Miranda* rights by determining whether the waiver of rights was made intelligently and knowingly. Intellectual disability, psychosis, mania, or severe depression may impair a defendant's ability to intelligently and knowingly make a decision to waive his or her *Miranda* rights. An incompetently made confession or incompetent waiver of *Miranda* rights may lead a court to rule a defendant's prior confession inadmissible at trial.

COMPETENCE TO PLEAD GUILTY

Many defendants plead guilty in exchange for a reduced sentence or dismissal of part of the indictment in the process known as plea bargaining. Pleading guilty involves waiving specific rights, including the privilege against self-incrimination; right to a jury trial; and the right to confront witnesses.

Clinicians may contemporaneously evaluate a defendant's competence who wishes to plead guilty, or (more frequently) retrospectively evaluate a defendant's competence to plead guilty as the basis of an appeal. At issue is whether the defendant had a mental disorder at the time that the decision to plead guilty was made, and whether the symptoms of the defendant's mental disorder impaired his or her ability to intelligently, knowingly, and voluntarily waive those rights (*Johnson v. Zerbst* 1938).

In *Godinez v. Moran* (1993) the Supreme Court rejected the notion that competence to plead guilty must be measured by a standard that is higher than (or even different from) the *Dusky* standard. The Court articulated that although a decision to plead guilty is undeniably a profound one, it is no more complicated than the sum total of decisions that a defendant may be called upon to make during the course of the trial.

COMPETENCE TO WAIVE COUNSEL

The Sixth Amendment affords criminal defendants the right to counsel. The purpose of counsel includes assisting the defendant through the adjudicative process and ensuring the validity of the plea and court process (*Faretta v. California* 1975). Defendants may waive counsel for numerous reasons, including mistrust of the legal system; financial reasons; assertion that they are innocent and do not need counsel; belief that they could represent themselves better than an attorney; belief they will earn sympathy by

proceeding *pro se* against the government; or, any number of rational or psychotic beliefs.

In *Faretta v. California* (1975) the U.S. Supreme Court held that a criminal defendant has a Constitutional right to knowingly and intelligently refuse legal representation. Note that refusing counsel is not the same as representing oneself. The *Faretta* court added that a defendant's ability to represent himself or herself has no bearing on the defendant's competence to elect to represent himself or herself. In *Indiana v. Edwards* (2008), the Supreme Court ruled that courts may require a higher standard of competence for self-representation than that necessary for trial competence. The right to represent oneself is not absolute; courts have discretion in maintaining the validity of the court process.

Clinicians evaluating competence to waive counsel should familiarize themselves with jurisdictional law. Under *Faretta*, the clinician evaluating competence to waive counsel must assess whether the defendant understands that he or she is abandoning the right to representation by legal counsel and that there may be disadvantages of this decision. Although the evaluator may not agree with the defendant's rationale, the evaluator must be careful not to equate poor judgment with incompetence. Rather, the focus should hinge on whether the defendant has a mental illness that impairs the decision to intelligently waive counsel.

COMPETENCE TO WAIVE A JURY TRIAL

The U.S. Constitution guarantees the right to be tried by an impartial jury of one's peers but does not guarantee the right to waive a jury trial. Defendants may seek to be tried by the trial judge if they perceive that a bench trial is in their legal interests, which is frequently the case in contested insanity trials. There is not a specific legal standard to waive the right to trial by jury. Extrapolating from other legal standards, a defendant who waives trial by jury must make the waiver intelligently, knowingly, and voluntarily (*Johnson v. Zerbst* 1938).

The clinician assessing whether a defendant can competently waive trial by jury evaluates whether the defendant has a mental disorder that impairs the ability to understand the right to be impartially tried by a jury of one's peers, and investigates the rationality of the decision.

COMPETENCE TO BE SENTENCED

A defendant who is competent to stand trial or to plead guilty may experience an exacerbation of illness during the time between trial and sentencing, and subsequently become incompetent to be sentenced. Competence to be sentenced deals with evaluating the defendant's understanding that he or she has been convicted of a crime; the reason for the conviction; and the reasons that a sentence will be imposed. Competence to be sentenced requires that the defendant be able to rationally participate in a presentence investigation; to assist the defendant's defense attorney in minimizing the negative impact of their conviction; and to assist the attorney in offering mitigating factors that may cause the court to reduce their sentence.

COMPETENCE TO WAIVE APPEALS

Defendants who have been convicted may appeal their conviction. Defendants who are convicted and sentenced to death have numerous appeals filed automatically on their behalf. A mentally ill defendant may irrationally instruct his or her attorney to not file appeals, or may refuse to cooperate with his or her attorney in preparing appeals. In contrast, a defendant may rationally waive his or her appeals in the belief that pursuing further appeals is not likely to be fruitful or in his or her best interests.

Evaluating competence to waive appeals involves assessing the defendant's current mental state and understanding if current symptoms impair the defendant's ability to rationally make a decision whether to pursue appeals and to assist the defense counsel in that pursuit. A depressed defendant who, as a result of his or her depression, lacks energy/motivation to pursue appeals may be incompetent to waive appeals. A suicidal defendant seeking capital punishment may be incompetent to waive appeals, as is a defendant with paranoid delusions about his or her attorney or the court. In contrast, a defendant who prefers capital punishment compared to a life of imprisonment may be competent to waive appeals if his or her decision is rational and not the product of a mental disorder.

COMPETENCE TO BE EXECUTED

Presently, 31 states and the federal jurisdiction may impose the death penalty. In American jurisdictions, 15 years, on average, pass between when the defendant is sentenced to death and when the sentence is carried out. Defendants on death row may develop a mental disorder that may impair their competence to be executed.

The U.S. Supreme Court has ruled that executing a mentally retarded defendant is unconstitutional (*Atkins v. Virginia* 2002), as is executing a defendant who was under the age of 18 years at the time of the commission of the offense (*Roper v. Simmons* 2005).

In *Ford v. Wainwright* (1986), the U.S. Supreme Court ruled that it is cruel and unusual punishment, in violation of the Eighth Amendment, to execute an incompetent defendant, and that states must have sufficient procedures in place to allow a defendant to challenge his or her competence to be executed. The *Ford* Court held that the trial court should determine the defendant's competence to be executed by evaluating the defendant's understanding of the nature of the death penalty and the reason that the death penalty is being imposed.

In *Panetti v. Quarterman* (2007), the U.S. Supreme Court broadly interpreted their ruling in *Ford v. Wainwright*, indicating that a defendant's simple awareness of the state's rationale for the execution was insufficient to prove that the defendant is competent to be executed. Instead, a defendant

must have a more substantive understanding of the nature of the death penalty and the reason for its imposition. Although not giving a bright-line definition of what a more substantive understanding of the death penalty constitutes, the Court held that simple "yes" or "no" responses by the defendant to a series of questions about the death penalty do not constitute a substantive understanding of the death penalty.

Forensic evaluators may be called upon to evaluate a defendant's competence to be executed. Such an evaluation should assess the defendant's mental state and the presence or absence of a mental disorder that may impact the defendant's understanding of:

1. The general concept of punishment
2. The nature of the death penalty
3. The nature of death row
4. The personnel present at the execution
5. The role of the defense attorney
6. What will happen when his or her execution is carried out
7. The reason that the death sentence has been imposed
8. Symptoms that may impact his or her perception of reality

SUMMARY KEY POINTS

- Competence to stand trial is one of the most common forensic mental health assessments.
- The clinician evaluating any of the criminal competencies must know the competence legal standard in the jurisdiction.
- Evaluating criminal competencies typically involves assessing the defendant's present mental state, although retrospective competence evaluations may be an issue.
- Mental illness does not equate with incompetence. Incompetence requires impairment of the specific mental functions operative for the specific competence.
- Incompetence to stand trial requires that a defendant either be unable to understand the nature and objectives of the court proceedings, be unable to assist in his or her defense, or both.

Treatment for restoration of competence to stand trial

KELLY GOODNESS AND ALAN R. FELTHOUS

INTRODUCTION

Perhaps the largest forensic population requiring treatment consists of criminal defendants who have been found incompetent to stand trial (Torrey et al. 2010). Since the landmark case of *Jackson v. Indiana* (1972) that prevents individuals from being denied due process by holding them for unconscionably long time periods with no hope of attaining trial competence, a fair amount of attention has been directed to ascertaining the factors that are most associated with findings of incompetence, identifying who is likely to attain competence and in what period of time (Zapf 2013). Yet disturbingly little scholarly effort has been devoted to detailing model restoration programs or empirically deriving efficacious treatment modalities (Pinals 2005; Brinkley and DeMier 2009; Samuel and Michals 2011). Although much of competence restoration consists of the sound principles of mental health practices in general, there are aspects specific to competence restoration which require specialized training if the programs and interventions are to be effective, efficient, and adherent to legal requirements and ethical principles.

Competence to stand trial

There are two legal issues involved in the treatment for, and restoration of, incompetence to proceed. First, individuals who are incompetent to stand trial due to mental illness or defect can only enjoy a meaningful defense and due process if they are afforded treatment that allows them to meaningfully participate in their defense. Restoration to trial competence is the process of applying psychiatric and/or psychological treatment to those symptoms identified as barriers to a defendant's ability to legally proceed through the system. Second, the government has an interest in the prosecution and adjudication of criminal defendants, and thus has an interest in ensuring that incompetent defendants attain adequate competence. Although there is significant overlap between treating psychiatric patients in general and the treatment of incompetent defendants; there are important differences given the legally mandated goal of the treatment. The treatment may or may not serve the individual's best legal interests, and treatment providers may feel torn between meeting the legal mandate and addressing the full array of the patient's needs. Moreover, the government's interest in adjudicating an individual does not mean treatment is automatic, and ethical treatment providers must have an understanding of relevant case law.

WHAT DATA ARE RELEVANT TO THE LEGAL CRITERIA?

The data relevant to the legal criteria include the individual specific symptoms and deficits that negatively impact competence-related capacities, amenability to treatment, and the expected time required for treatment. Each of these can be impacted by the location in which treatment takes place as well as the defendant's desire to accept treatment.

The standard by which trial competency is judged was outlined in *Dusky v. United States* (1960) wherein the court concluded that "the test must be whether he has sufficient present ability to consult with his lawyer with a reasonable degree of rational understanding—and whether he has a rational as well as factual understanding of the proceedings against him" (p. 789). *Dusky* resulted in requiring a functional analysis of how symptoms of mental illness or defect impact competence-related capacities, and subsequently a number of jurisdictions have provided further guidance.

A mental disorder alone, or the mere presence of symptoms, does not equate to incompetence. The specific symptoms of mental illness or defect that negatively impact an individual's trial capacities must be identified. For example, some individuals will always have some level of hallucinations, but can be taught coping strategies, such as reality testing, in order that their hallucinations do not greatly interfere with trial capacities. Individuals with psychotic disorders are nearly eight times more likely to be found

incompetent than individuals without a psychotic disorder, and those with a prior psychiatric hospitalization are nearly twice as likely to be found incompetent (Pirelli et al. 2011). As such, the use of antipsychotic medications has been the predominant treatment. However, several legal cases have addressed the issue of *voluntariness,* and have placed limits on the use of pharmacological interventions as the sole or primary intervention for competence restoration, making voluntariness relevant to the legal criteria.

Most jurisdictions place limitations on the available time for competence restoration, and many translate that to the amount of time the individual could have served if found guilty of his or her charges. Fortunately, available studies have found that overall competence restoration rates are high, with 75%–90% of individuals typically being restored in 6 months or less of inpatient restoration treatment (Pinals 2005; Mossman 2007). Zapf (2013) recently analyzed the average length of stay (LOS) for defendants admitted for competence restoration at Eastern State Hospital in Washington State over a 24-year period. She found an average LOS of 89.2 days for felony defendants who were restored to competency and a much quicker 29 day average LOS for misdemeanor defendants who attained competence. Morris and DeYoung (2014) studied 81 individuals who had failed restoration efforts after 6 months and found that the majority (64.2%) were eventually deemed restored to competence with extended restoration efforts. They found the utility of treatment maxed out at 3½ years, which suggests that there is a relatively small subset of individuals who are never able to attain competence. Individuals with organic dysfunction, severe cognitive impairment, or chronic psychosis are most likely to fall into the unrestorable category (Mossman 2007).

Competency to stand trial restoration overview

NO UNIFORM STANDARD OF PRACTICE

The fact that there is no uniform standard of practice for constructing treatment for competence restoration has been highlighted in multiple studies. In a recent study conducted by Samuel and Michals (2011) of 27 forensic programs, the need for standardization of programming and staff training was highlighted. Of the participating programs, only two of the 11 described themselves as well-organized with ongoing research, and they were the only two that distributed instructional handouts on a regular basis. Not surprisingly, only two programs provided any formalized training to staff who led competency training. Likewise, only two programs provided actual supervision of restoration staff through videotape or observation to ensure quality control. Only three programs utilized a standardized competency evaluation instrument. Interestingly, only three programs consulted with their patients' attorneys, even though all programs recognized doing so would be of "great importance." Though only a pilot study, Samuel and Michals' work highlights the need for greater standardization of practice, quality control, and importantly, the need for consistent training and supervision of restoration staff.

LOCATION OF TREATMENT

Since the deinstitutionalization of the mentally ill, more individuals with severe and persistent mental illness are becoming involved with the criminal justice system, and that system is increasingly bearing the responsibility for the care of our mentally ill citizens (Torrey et al. 2010). The mechanism through which many seriously mentally ill individuals ultimately receive psychiatric care is through a court's finding of criminal trial incompetence. The traditional location of competence restoration treatment has been psychiatric hospitals. Hospital-based treatment generally allows for more access to programs such as group and individual psychotherapy and more frequent contact with mental health providers. This treatment milieu is almost always more conducive to healing than a penal institution, and arguably the support staff should be better trained in dealing with mental illness. However, the need for bed space for incompetent patients has increased while resources have decreased, often making for long wait times before treatment. As a matter of necessity and in attempts to obtain more expeditious, humanitarian treatment, alternative treatment settings have been sought in jail-based and community-based programs.

Jennings and Bell (2012) detailed a comprehensive jail-based treatment program model entitled Restoration of Competency (ROC) that called for the provision of intensive psychiatric stabilization, forensic evaluation, and restoration and maintenance of competency within a local jail. The ROC model was developed as a pilot project in the 1990s and called for the transformation of a jail pod into a mental health facility that essentially mirrored many services usually provided in a hospital. Much like the Social Learning Diagnostic Program described by Goodness and Renfro (2002), the ROC program included team-based treatment in a therapeutic milieu that utilized a positive reinforcement management system to encourage and reward meaningful participation. Patients received active medication management and 3.5–5.5 hours daily of group-based rehabilitative activities aimed at both mental health issues and legal competence capacities. Jennings and Bell's 5-year outcome study showed that the program achieved an 83% overall competence restoration with an average treatment length of 77 days.

Depending on the extent of services, the benefits of jail-based competence restoration can include lower costs, reduced waitlists for hospital beds, decreased length of time to restore competence, elimination of incentives to malinger, seamless transition from competence restoration to adjudication, and assistance of local jail staff in better managing a population that requires specialized knowledge (Jennings and Bell 2012). The disadvantages of jail-based restoration include the general austerity of a penal institution, high noise levels, and the reality that jails are built to provide security versus the sort of supportive surroundings that are conducive to healing (Kapoor 2011). Moreover, not all jail-based

programs are well organized or comprehensive, and some clinicians have questioned if restoration can be successfully accomplished in jail (Kapoor 2011). Additionally, jail medical staff may resist participating in competence restoration efforts as they face ethical quandaries when asked to set aside the patient's stated desires and potential best interest and focus on the goals of the justice system.

Some community-based competence restoration programs (CBCRPs) have begun to serve individuals who do not have violent charges. Programs are run by the state mental health agency and include case management that follows more of an intensive Assertive Community Treatment model wherein the patient is provided close medication oversight, transportation to medical appointments, individual instruction in legal rights and factual competence issues, and individually tailored interventions (Miller et al. 2009). Potentially destabilizing factors may be targeted, such as housing, unemployment, substance abuse, and the need for appropriate social activities. Community-based programming frees inpatient bed space, is less costly than inpatient restoration, and is more recovery oriented (Miller et al. 2009), which may offer at least some individuals an alternative that helps to address the reasons for the revolving door process between the criminal justice system and intermittent mental health treatment. Aside from budgetary barriers, CBCRPs have faced challenges through limited buy-in from courts, and some legal professionals may be attempting to circumvent *Jackson v. Indiana* through placement of neuropsychologically impaired individuals in nursing homes ostensibly for outpatient competence restoration.

Elements of competency restoration

Much of the scant literature regarding competence restoration treatment is descriptive in nature (Brown 1992; Noffsinger 2001). The studies meant to test treatment efficacy are often problematic due to methodological design issues, including lack of experimental control groups, small sample sizes, and poor outcome measures, making it impossible to draw firm conclusions. A case in point can be found in an often quoted study by Bertman et al. (2003) in which the authors made the first peer-reviewed efforts to evaluate what they asserted was the effectiveness of individualized treatment for the restoration of competency. Though prior authors have cited this study as an argument against individualized treatment plans, the reality is that Bertman's study included three groups of very small *n* of 10 or less, with little statistical difference between the groups. Moreover, their definition of six training sessions being individualized treatment is overreaching by generally accepted clinical treatment standards. This study simply does not allow for a global discarding of individual approaches. Indeed, most clinicians might support the notion that tailoring treatment for individual clinical concerns is paramount for effective intervention regardless of why a patient is in treatment.

Empirically examining psycholegal competency interventions poses many legal and clinical challenges (Scott 2003) and is a formidable task, especially as many who are best positioned to conduct such research are so busy with direct care services that little time is left to conduct research. However, this task should become a priority given the increasing number of individuals likely to enter treatment through the criminal justice system as incompetent to proceed. As demand increases and resources do not, resources should be expended on treatment efforts with statistically proven efficacy. Moreover, utilizing efficacious treatments is ethically incumbent upon clinicians, and "forensic clinicians engaged in competency restoration treatment need to be able to articulate the scientific basis for their interventions" (Brinkley and DeMier 2009, 388). Still, until time has allowed for greater empirical study, the legal push for alternatives to treatment based on medication only, our collective forensic clinical experience and, to a large extent, common sense, lead us to advocate for including all or some of the components described below in the treatment for and restoration of competence to stand trial. Many of these elements can be utilized regardless of whether treatment occurs in a community, jail, or hospital setting.

INITIAL ASSESSMENT AND TREATMENT PLANNING

The central goal of competence restoration treatment is to achieve an adequate level of factual and rational competence. Successful competence restoration does not require that treatment produce a perfect defendant, and the court's order does not generally authorize treatment to maximum personal benefit. Instead, treatment should be geared toward eliminating symptoms where possible and lessening residual symptoms that negate trial competence.

Generally, defendants are ordered into treatment after a relatively brief forensic examination of their competence-related capacities. These initial evaluations may be done under less than desirable conditions, including time pressures, noisy and chaotic jail environments, and little to no documentation of background information or prior treatment efforts. Thus, these evaluations may vary greatly in quality and may not provide a very good understanding of the patient's functioning. Moreover, by the time an individual actually enters treatment, his or her clinical presentation may be better or worse. Treating clinicians should consult the evaluations that formed the basis for commitment to treatment to ascertain what symptoms were identified as being of most concern to the court. However, we recommend treating clinicians conduct a comprehensive initial evaluation and devise a treatment plan to address the specific symptoms and deficits that negatively impact an individual's trial competence.

Deficits in factual competence are generally easy to identify. Factual understanding focuses on basic legal concepts such as the roles of attorneys and judges and the meaning of guilty and not guilty pleas, and deficits are often a matter of education or rote memorization. Deficits in rational competence can be more difficult to identify. Rational understanding is a higher-order ability than factual understanding because it requires that an individual have the capacity to

understand, process, and logically apply information to his or her own case rather than simply memorize and parrot back facts.

A diagnostic interview and mental status evaluation will certainly inform the individual's overall mental health treatment. In addition, an objective, standardized trial competence assessment instrument should be administered when the defendant first arrives in order to guide treatment planning by systematically identifying deficits that contribute to the defendant's incompetence (Pendleton 1980; Noffsinger 2001). There are several such instruments from which to select, each having its own strengths and weaknesses (Pirelli et al. 2011). Indeed, "[n]ot all defendants are incompetent for the same reason, and therefore the underlying reason leading to each defendant's incompetence should be identified by an objective competence assessment upon admission to the program" (Noffsinger 2001, 360–361). Importantly, such instruments can be repeated throughout treatment to gauge progress.

Be it due to prior noted concerns, concerns that arise during the initial evaluation, or those that arise at some point in treatment, it may be necessary to place the patient on a malingering protocol as a part of his or her treatment plan to rule out (or in) the possibility of symptom exaggeration. Malingering protocols may include increased documentation by direct care staff, observation via closed-circuit cameras, and analysis of the consistency of behavior throughout the work shifts and over time so that a broad sample of the individual's behavior can be assessed. A malingering protocol can sometimes provide more useful information than administration of standardized malingering instruments.

Cultural barriers can impact mental health functioning and treatment engagement, which in turn can negatively impact competency capacities. At its most basic level, cultural issues can involve language barriers that affect the ability to communicate important facets of the person's life and background that may inform treatment (American Psychological Association and Jansen 2014). Clinicians must be sensitive to increased social stigma in some cultures regarding behavioral health problems or religious beliefs that impact treatment acceptance, treatment needs, and recovery (American Psychological Association and Jansen 2014). Appropriate provisions should be made for interpreters adequately trained in assisting mental health providers. Likewise, utilization of language-specific psycholegal materials aids the necessary acquisition of factual knowledge.

Treatment providers should not be hesitant to contact the involved attorneys or the court for information. Defense attorneys can provide important information regarding difficulties the patient may have had in consulting with counsel. It can be frustrating for treatment teams when an individual who they believe has been successfully restored is repeatedly court ordered into treatment as incompetent for reasons that may not have been well articulated to the hospital. By the same token, the court may repeatedly be mystified why the individual has been returned with a recommendation of competent to proceed if reports to the court were unclear, or in some cases because documentation had simply never been fully read. Increasing communication and collaboration with the stakeholders has been shown to resolve issues and improve outcomes and processes (Olley et al. 2009). "When the mental health and legal systems collaborate effectively, the entire competency process improves" (Finkle et al. 2009, 780).

PHARMACOTHERAPY

Research clearly indicates that successful restoration is often related to how well an individual's symptoms respond to psychotropic medications. Thus, an essential component of treatment for restoration of competence of most defendants who are found incompetent to stand trial is pharmacotherapy. Selecting the most appropriate medication and managing its administration is to a large extent simply a matter of accepted pharmacotherapy for mental disorders in general, which is well described in any current standard textbook of psychopharmacotherapy. Here we encourage currency in modern pharmacotherapy, but focus this discussion on consideration of special relevance to competence restoration.

Most defendants are incompetent due to schizophrenia or other psychotic or serious thought disorder. Proper treatment of the disorder, usually involving an antipsychotic, will at the same time improve the defendant's ability to think realistically and rationally such that his or her main incapacity for competence will be restored. The core symptoms resulting in incompetence are often the defendant's psychosis and disturbance of thought. However, extreme disturbance of mood or emotional and behavioral control can also impair the defendant's ability to assist in his or her defense and cloud the defendant's ability to think clearly and adaptively. However, even those conditions that cause suffering and other significant disability, such as nightmare disorder, ought to be treated while the defendant is in treatment, even if such disorders do not directly contribute to his or her incompetence. Humanitarian treatment and standard of care apply, even as the main goal of treatment is restoration of competence, and the main determinant for the defendant's readiness to be returned to court and trial is the restoration of his or her competence to stand trial.

Physically aggressive and violent behavior does not *per se* render a defendant incompetent to stand trial. Yet it must be addressed for safe and effective treatment management. Its efficacious pharmacotherapy, where indicated, can improve the defendant's psychological functioning such that it favorably strengthens abilities needed for competence. For safe, effective, and timely treatment of clinical aggression, it is recommended that the assessment of the nature of the aggression be initiated even before the defendant arrives at the hospital for admission (Felthous et al. 2009). A critical distinction must first be made between impulsive aggression which is often improved with appropriate pharmacotherapy and premeditated aggression, which without other mental disorders, is not (Felthous and Barratt 2003).

Once the aggression is determined to be impulsive, as most aggression in security hospitals appears to be

(Felthous et al. 2009), evaluators should determine whether the impulsive aggression is primary or secondary to another mental disorder (Felthous 2013). The specific drugs that have repeatedly demonstrated efficacy in the treatment of primary impulsive aggression include fluoxetine, lithium, phenytoin, carbamazepine, and valproate/divalproex (Felthous et al. 2013). Especially because no drug is U.S. Food and Drug Administration (FDA) approved for the treatment of primary impulsive aggression or intermittent explosive disorder (American Psychiatric Association 2013), an algorithm has been proposed to assist in selecting the most appropriate anti-impulsive aggressive agent (AIAA) for the individual patient (Felthous and Stanford 2015). Moeller and Swann (2007) developed an algorithm that is useful for the pharmacotherapy of secondary aggression, which has also been discussed in the context of correctional psychiatry (Felthous 2013).

Defendants who are remanded to a hospital for competence restoration typically have a serious mental disorder or defect, not impulsive aggression alone. In other words, if they show impulsive aggression this is often related to their primary mental disorder such as bipolar disorder or schizophrenia. Accordingly, the aggression will likely come under control with efficacious treatment of the primary disorder (Moeller and Swann 2007; Felthous 2013). If not, an AIAA can be added to the regimen with appropriate consideration (Felthous 2013) and the awareness that no AIAA is FDA approved for this use. Also to be borne in mind, risperidone (Moeller and Swann 2007) and olanzapine (Volavka et al. 2016) have been shown to help curb aggressive behavior, and clozapine has a remarkably anti-aggressive effect (Fava 1997) for mentally disordered individuals for whom such antipsychotics are otherwise indicated. Much of the evidence for clozapine's anti-aggressive efficacy derives from its use in treating schizophrenia (Volavka et al. 2004). Evidence suggests that clozapine may have anti-aggressive effects for other severe mental disorders, not just schizophrenia (Rabinowitz et al. 1996; Hector 1998).

Three landmark cases must be kept in mind when determining medically, ethically, and legally appropriate treatment in each case, as they underscore the need to explore alternative treatments for competence restoration versus solely relying on psychotropic medications. First, in *Washington v. Harper* (1990), the Supreme Court established that an individual has a constitutionally protected "liberty interest" in "avoiding the unwanted administration of antipsychotic drugs" (p. 221) and that those interests must be balanced against the state interests as the two may not be compatible. The importance of *Harper* was its attempt to define what criteria and procedures are constitutionally required to medicate a prisoner against his refusal. In *Harper*, the court found that under certain conditions, individuals could be involuntary medicated if they were dangerous to themselves or others, and medication was appropriate medical treatment. In *Riggins v. Nevada* (1992), the court found competency restoration did constitute "an important state interest" under certain conditions.

In *Sell v United States* (2003), the Court ruled that four criteria must be met before the government may override a "nondangerous" incompetent defendant's refusal of treatment with antipsychotic medication: important governmental interests are at stake; forced medications are substantially likely to render the defendant competent, while side effects are substantially unlikely to significantly interfere with the defendant's ability to assist counsel with his or her defense; there are no less intrusive treatments likely to achieve substantially the same results as medications; and administration of medication is medically appropriate.

EDUCATIONAL COMPONENT

Competence restoration generally should include educational components that can be delivered via a number of modalities. Although not all defendants will require psycholegal education, many need assistance in recognizing the application of legal concepts to their own situation. Requisite knowledge is both general, what any defendant should know, and specific, what individual defendants should know about their particular legal situation. General knowledge should include education about the elements of various types of charges, their severity, and the potential legal consequence associated with various charges; the standard pleas and the significance of each, the plea bargaining process; the roles of the principles in the courtroom; courtroom procedures and the nature of the adversarial trial process, and evaluating evidence (Davis 1985; Brown 1992; Noffsinger 2001).

Knowing what specific knowledge an individual needs to acquire requires some understanding of his or her legal case and how his or her symptoms negatively impact the defendant's ability to rationally work through the necessary decisions and issues. For example, it may not be clear that a defendant has delusions about individuals related to his or her case unless the defendant's specific case is discussed. Therefore, attending only to generalized knowledge may be insufficient to bring about trial competence or make continued incompetence clear. Pinals (2005) noted that clinicians who "are not familiar with competence or competence restoration may inadvertently ignore a significant issue in their patient's lives. When this occurs, by the time the patient's court case is slated for review, significant periods of time could have passed without any clinician speaking to the patient about the criminal charge" (p. 86). A decade later, her point is unfortunately still a matter of concern. It is not uncommon to find that during even lengthy hospitalizations, seemingly no clinician has addressed a particular defendant's understanding of the case, yet the patient was returned to the court with a recommended finding of competent to proceed.

Individual instruction for factual competence training is often accomplished through didactic groups. A competence education class may include written handouts or didactic lectures describing the legal process. Group problem-solving sessions utilizing issues that arise in participant's actual cases may be helpful (Siegel and Elwork 1990). Discussions

regarding news stories involving criminal trials have also been utilized (Noffsinger 2001).

Some competency restoration programs have become more standardized or manualized than the available peer-reviewed literature reflects. This likelihood is reflected in the CompKit (2012) developed by Florida State Hospital with the assistance of multiple other agencies. The CompKit package includes separate written materials for instructors and consumers, a CD of the materials, and a DVD of movies involving mock hearings/trials and a competency training television game show. The CompKit has been updated several times and has been widely disseminated for use by interested providers.

A novel, potentially useful approach to teaching the knowledge needed for competence to stand trial is the Fitness Game developed by Cuneo and Owen (1990). It is a participatory game designed much like the board game Monopoly, where players learn about legal proceedings as the game progresses. The true effectiveness is in question, based on Meuller and Wylie's (2007) study of incompetent defendants in a state hospital. They found no significant difference on competency measures between the Fitness Game and a similarly designed game that targeted general mental health behavior such as symptom management, and treatment compliance (p. 897). Still, it may be helpful to utilize an engaging game as part of a multimodal treatment plan, and certainly could not cause harm.

EXPERIENTIAL COMPONENT

Noffsinger (2001) recommends competence restoration programming be multimodal, incorporating a broad selection of teaching methods that are delivered by multiple staff members in order to increase interest and retention. As such, adding experiential techniques may prove beneficial. Behavioral rehearsal through role-play or mock trials may assist in teaching interpersonal skills that allow the patient to better relate to and work with defense counsel while also increasing their understanding of expected courtroom behavior and procedures. Videotaped vignettes can teach basic legal procedures, add variety to training, and decrease anxiety regarding the legal setting (Noffsinger 2001). Mock trials can be conducted by treatment staff, though lawyers and judges have participated at some institutions. Staff may take on the major roles such as judge, prosecutor, or defense attorney, while patients participate as members of the jury, the bailiff, or the defendant (CompKit 2012). Best practices call for staff (paraprofessionals and licensed professionals alike) to be provided with specific training and ongoing supervision. Periodic quality checks to ensure that the interventions are being administered competently and as intended should be built into any program.

PSYCHOTHERAPY COMPONENT

Some patients would benefit from cognitive behavior therapy or other talk therapies in order to adequately uncover and work through irrational notions or excessive emotionality. Although anxiety reduction techniques (i.e., progressive relaxation, imagery) taught in a group setting may be sufficient for some patients, others may have psychological issues that appear to be interfering with competency restoration that would be better addressed through individual psychotherapy. An investment in individual psychotherapy could potentially go far in addressing the revolving door process between treatment noncompliance, legal charges, and court-ordered competence restoration treatment while also allowing for more intensive psychoeducation.

COGNITIVE REMEDIATION

Schwalbe and Medalia (2007) advocated using cognitive remediation as an adjunctive treatment in restoration programs. Cognitive remediation involves mental exercises that are meant to improve attention, memory, and problem solving, which may improve a patient's ability to retain information related to trial competence. Originally, cognitive remediation techniques were developed to assist individuals who had sustained neuropsychological injury, but have since been used with those with psychiatric illness such as schizophrenia. Schwalbe and Medalia advocate the use of the Neuropsychological Educational Approach to Cognitive Remediation (NEAR) model, as it was specifically designed for use with psychiatric patients who may, perhaps due to the illness itself, lack the intrinsic motivation necessary for repetitive drill exercises. The NEAR model is thought to be more stimulating, dynamic, and enjoyable because exercises are presented in real-life contexts in several different formats (via computer and verbal groups), and within a small group format that allows for interaction with others.

INDIVIDUALS WITH INTELLECTUAL DISABILITIES

Trial competence attainment can be particularly challenging, though not impossible, for individuals with developmental disabilities. The extent to which competency attainment efforts are successful with this group often depends on the severity and type of disability, which can be complicated by a comorbid psychiatric disorder. In general, one-third of individuals with developmental disabilities are believed to be able to attain competence to proceed (Zapf 2013). The Slater Method is a formal competency training tool specifically designed to address the difficulties encountered by persons with intellectual impairments (Wall and Christopher 2012). The Slater Method includes five modules: the purpose of the training, review of the charges, pleas, and potential consequences; courtroom personnel; courtroom proceedings, trial, and plea bargain; communicating with the attorney, giving testimony, and assisting in defense; and tolerating the stress of the proceedings. Each module is presented in sequential order a minimum of three times in order to engage in repetitious learning and improve retention. Wall and Christopher (2012) conducted a small retrospective study of mentally retarded or borderline intellectual functioning patients hospitalized for competence

restoration. Patients treated through the Slater Method were more than 3½ times more likely to attain competence than those who were treated through traditional treatment alone. Their findings suggest systematic, programmed efforts at competence attainment are useful with those who have intellectual disabilities.

PERIODIC RE-EVALUATION AND DOCUMENTATION

The ethic of compartmentalizing forensic from therapeutic roles should not distract from the responsibility of measuring treatment progress and correspondingly documenting results in the health record. All treatment efforts, including observations made in group therapies (Pinals 2005), pharmacotherapeutic adjustments, and the patient's response, should be documented to accurately reflect the individual's daily physical and emotional functioning. This information is needed to track progress and inform treatment. Utilization of a standardized competence assessment instrument at periodic intervals is recommended to monitor progress toward attainment of competence to stand trial.

Pinals (2005, 85) wrote eloquently about some of the ethical struggles of clinicians who are charged with treating incompetent defendants in that clinicians "working as allies of their patients, ethical tensions arise in the notion that one of their jobs may be to help their patients regain competence to stand trial, which could culminate in an adjudication of guilt and possible incarceration or capital punishment for a particular patient." One of the primary mechanisms to deal with the ethical push/pull between the patient's treatment goals/needs and the goals of the criminal justice system is separating the roles of the patient's treating clinicians from that of their forensic evaluator who issues an opinion regarding competency to the court. All mental health professionals, regardless of professional affiliation, are ethically prohibited from entering into the dual roles. However, this does not mean that forensic treatment and forensic assessment should be completely compartmentalized, as such would mean the timing of restoration would lose efficiency and needlessly prolong treatment. There is a significant difference between assessing and documenting a patient's progress in meeting treatment goals and formally evaluating, articulating, and opining to the court whether or not an individual meets the standard for competence to proceed. Certainly, the latter evaluation should be conducted by an evaluator who is not involved in the patient's treatment.

Care should be taken to protect the individual's Fifth and Sixth Amendment rights to avoid unnecessary documentation of statements made by an incompetent defendant in the throes of illness. Care providers should remain mindful that the individual has been court ordered into treatment, and the records may ultimately be reviewed by legal professionals and used in ways that are difficult to anticipate. For example, documenting assertions of guilt or complicity would usually serve no clinical purpose.

SUMMARY KEY POINTS

It is our hope that by the next edition of this book, more empirically driven treatments will have been identified, and structured competency restoration programs will be the norm.

- Most individuals can successfully attain or be restored to competence to stand trial.
- Accurate and timely assessment and reassessment of symptoms and deficits are key to efficient treatment.
- Pharmacotherapy that follows the current state of the science is usually necessary but must be administered within the confines of the law.
- Nonmedication treatment modalities can be helpful and should address individual-specific symptoms and deficits.

Criminal responsibility

ALAN R. FELTHOUS

INTRODUCTION

This chapter begins with the historical development of the insanity defense, the M'Naghten Rule, and then explains the irresistible impulse test, contemporary insanity defense standards in the United States, including variations in the M'Naghten standard and judicial interpretations of wrongfulness. Other mental defenses include partial responsibility variants, heat of passion, extreme emotional disturbance, and guilty but mentally ill. Issues with relevance to criminal responsibility include voluntary and involuntary intoxication, settled insanity, impulse control disorders, disturbances in consciousness, the battered wife syndrome, and organized psychosis.

ORIGINS OF THE INSANITY DEFENSE

The insanity defense in the United States derives from English common law but also from Medieval and ancient theologies in Europe and the Middle East. Today the insanity defense is not only a central component of U.S. criminal jurisprudence, but a defense that has been incorporated into the criminal law in many other countries as well (Felthous and Saβ 2014; Taylor et al. 2014). Thus the insanity defense, though often criticized and diminished, reflects widespread concepts of procedural fairness and criminal responsibility that have endured for centuries.

The ancient origins of criminal responsibility have both theological and philosophical roots. The theological foundation for the insanity defense has been traced back to the disobedience of Adam and Eve who, by exercising their "free will," defied God by eating the forbidden fruit from the tree of knowledge. Within the Judeo-Christian framework, this account in Genesis led to the concept of free will and criminal responsibility. Aristotle formulated a concept of criminal responsibility in the fourth century BCE that influenced the Western church in the Middle Ages and remains consistent with and supportive of modern concepts of criminal responsibility. He distinguished between voluntary and involuntary acts with respect to their blameworthiness (Aristotle 2004).

In Roman law, specifically the Justinian Code (Justinian, Digest 48.8.12), perhaps the first written law in which insanity was codified as an excuse for crime (Walker 1985), which preceded canonical law of the Roman Church, insane offenders had been treated with leniency because, although a "madman has 'no will'" (Digest 1.18.14, 27), the offender's insanity was considered to be punishment enough ("*satisfurore ipso punitur*" Walker [1968] citing the Digest [1.18.14]).

Already early in the eleventh century, well before the Norman Conquest of 1066, English law distinguished between misdeeds that are intentional, voluntary, and of one's own free will, and those that are the result of coercion or accident (Felthous 2008). In mid-thirteenth century Henry de Bracton's familiar test of insanity, the first published insanity standard in England, emphasized understanding: "An insane person is one who does not know what he is doing, is lacking in mind and reason and is not far removed from the brutes" (de Bracton 1879, 1016). King Edward III recognized that insanity was a complete defense to a criminal charge in the fourteenth century (Simon and Aaronson 1988). By 1500 juries began to acquit offenders based upon insanity (Walker 1985, 25), with the earliest recorded insanity acquittal by a jury in England having occurred in 1505 (Simon and Aaronson 1988).

The maxim "*actus non facitreum nisi mens sit rea*" (an act does not make one guilty unless his mind is guilty) (Coke 1669, 107) had become embedded in English common law by the mid-seventh century (Gardner 1993). In the seventeenth and eighteenth centuries English jurists continued to emphasize the importance of the will and the intellect in criminal responsibility (Felthous 2008). Sir Matthew Hale, the foremost English jurist early in the eighteenth century, who maintained that criminal responsibility required the will which in turn required understanding, provided in 1736 the first published insanity test in English law:

> [I]f these *dementes*... are totally deprived of the uſe of reaſon, they cannot be guilty ordinarily of capital offenſes, for they have not the uſe of underſtanding, and acꝛt not as reaſonable

> creatures, but their actions are in effect in the condition of brutes. (Hale 1736, vol. 1, 31)

From the eleventh through the eighteenth centuries, the will gave meaning and coherence to criminal responsibility, but insanity standards were based on understanding, upon which the will depended to function properly (Felthous 2008). Reminiscent of de Bracton's insanity standard formulated almost five centuries earlier, Justice Tracy formulated what became known as the "wild beast test" in his instructions to the jury in the *Arnold Case* published in 1724. To be found insane, the defendant must be found to be

> totally deprived of his understanding and memory, and doth not know what he is doing, no more than an infant … a brute, or a wild beast. (764–765)

Important in allowing insanity to be partial and not necessarily total (American Academy of Psychiatry and the Law 2014) was the delusion test of the *Hatfield* trial of 1800. That a criminal act could be excused if it were the product of a delusion without reference to awareness of the act's wrongfulness would later be related to the New Hampshire's and the short-lived District of Columbia's versions of the product tests.

In *Elements of Medical Jurisprudence* (Beck 1825), the first comprehensive American textbook on medical jurisprudence (Platt and Diamond 1966), Theodric Beck essentially approved the "right and wrong" test for insanity by favorably citing the use of this test in the English *Bellingham Case* (1812). By the early nineteenth century "right and wrong" had replaced "good and evil," and the former was the generally accepted test of insanity in U.S. courts during the first half of the nineteenth century.

THE M'NAGHTEN RULE

On January 20, 1843, a Scottish wood turner, Daniel M'Naghten, believed that he was being persecuted by the Tory Party of England and Sir Robert Peel, the prime minister and a Tory Party leader. M'Naghten shot and killed Edward Drummond, Peel's secretary. At trial he was acquitted based on insanity. Consternation over this verdict led Queen Victoria to summon 15 Law Lords in the House of Lords to respond to five questions about the insanity defense. Their response to two questions would become known as the M'Naghten Rule (American Academy of Psychiatry and the Law 2014):

> [E]very man is presumed to be sane…[T]o establish a defense on the ground of insanity, it must be proved that, at the time of the committing of the act, the party accused was labouring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing; or if he did know it, that he did not know he was doing what was wrong. (M'Naghten's Case 1843, 722)

The M'Naghten Rule of the House of Lords, serving as a model insanity standard, would eventually be adopted into law in England, most jurisdictions in the United States, and Commonwealth countries. It remains today the standard for the majority of states as well as the federal standard for the United States.

THE IRRESISTIBLE IMPULSE INSANITY STANDARD

Conceptually the irresistible impulse insanity standard had its historical psychopathological roots in the earliest studies of personality disorders. (For a fuller review see Saβ and Felthous 2007.) The first English case to use an irresistible impulse test was *Regina v. Oxford* in 1840, 3 years before the M'Naghten trial. In his successful insanity defense of Daniel M'Naghten, defense counsel Alexander Cockburn relied on the *Treatise on the Medical Jurisprudence of Insanity* by Isaac Ray, first published in 1838, in explaining M'Naghten's killing the Prime Minister's secretary as the result of an "irresistible impulse" (Diamond 1956). Almost immediately after the famous and influential M'Naghten Rule was announced, the Commonwealth of Massachusetts added the irresistible impulse rule (500, *Commonwealth v. Rogers* 1844).

Similarly, the District of Columbia would add an irresistible impulse test to its already in place M'Naghten rule cognitive test (*Smith v. United States* 1929). In *Fisher v. United States* (1946) the jury instructions further defined the irresistible impulse rule, wherein the mental illness overwhelmed or destroyed the defendant's will. By 1944, 17 states adopted the irresistible impulse test for insanity (Zilbourg 1944). Although some states combine a volitional or impulse-control disjunctively ("or") with a M'Naghten cognitive test for insanity, as of 1990 no state relies on irresistible impulse as its only test of insanity (American Academy of Psychiatry and the Law 2014).

THE MODEL PENAL CODE INSANITY STANDARD

Reminiscent of the dual cognitive/volitional pronged insanity standard of the Napoleonic concept of criminal responsibility (Felthous and Saß 2014), the American Law Institute (ALI) formulated its ALI standard in its Model Penal Code: "A person is not responsible for criminal conduct if at the time of such conduct as a result of mental disease or defect, he lacks substantial capacity either to appreciate the criminality (wrongfulness) of his conduct or to conform his conduct to the requirements of the law" (American Law Institute 1962). The Model Penal Code left to the states to decide whether to use "criminality" or "wrongfulness" in their insanity standards (*State v. Johnson* 1979). The "second paragraph" of the ALI test (Table 29.1) was intended to exclude a psychopathic personality disorder as a condition that would qualify for the insanity defense (*State v. Johnson* 1979).

Table 29.1 Insanity standards that contributed to insanity jurisprudence in the United States

Name of Standard	Year	Standard
Earliest Published Test in England	Thirteenth century	"An insane person is one who does not know what he is doing, is lacking in mind and reason and is not far removed from the brutes," de Braction, 1223/1224
"The Wild Beast Test"		"The defendant must be [found] to be '… totally deprived of understanding and memory and doth not know what he is doing, no more than an infant … a brute, or a wild beast …'" (Arnold's Case, 1724)
Good and Evil Test	1581	"If a mad man or a nautrallfoole, or a lunatic in the time of his lunacie, or a childe y apparently hath no knowledge of good or evil, do kil a ma, this is no felonious act nor any thing forfeited by it … for they cannot be said to have any understanding wil." (Eirenarche Code, Lambard)
The M'Naghten Rule	1843	"[T]o establish a defense on the ground of insanity, it must be proved that at the time of the committing of the act, the party accused was labouring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing; or if he did know it, that he did not know he was doing what was wrong." (M'Naghten Case, 1843)
The Durham Rule	1954	The Product Test "[A]n accused is not criminally responsible if his unlawful act was the product of mental disease or defect." (Durham v. United States, 1954)
The ALI Test	1962	"A person is not responsible for criminal conduct if at the time of such conduct as a result of mental disease or mental defect he lacks substantial capacity either to appreciate the criminality of his conduct or to conform his conduct to the requirements of the law." (American Law Institute, 1962) "The terms 'mental disease or defect' do not include abnormality manifested only by repeated criminal or otherwise antisocial conduct."
The Federal Standard	1984	It is an affirmative defense to a prosecution under any federal statute that at the time of commission of the acts constituting the offense, the defendant, as a result of severe mental disease or defect, was unable to appreciate the nature and quality or wrongfulness of his acts. Mental disease or defect does not otherwise constitute a defense. (Insanity Defense Reform Act of 1984)
Criminal Justice Mental Health Standards	1989	1. A person is not responsible for criminal conduct if, at the time of such conduct, and as a result of mental disease or defect, that person was unable to appreciate the wrongfulness of such conduct. 2. When used as a legal term in this standard *mental disease or defect* refers to: a. "impairment of mind, whether enduring or transitory; or b. mental retardation, either of which substantially affected the mental or emotional processes of the defendant at the time of the alleged offense" (American Bar Association, 1989)

CONTEMPORARY INSANITY DEFENSE STANDARDS IN THE UNITED STATES

Within the past half century the greatest change in insanity jurisprudence in the United States took place soon after John Hinckley's attempted assassination of President Reagan and subsequent insanity acquittal in 1982. Several state and the federal ALI insanity standards were changed by dropping the volitional prong but leaving the cognitive prong of the ALI insanity standard in place. In such jurisdictions this effectively replaced the volitional component with the M'Naghten standard. However, even where the functional component of the ALI standard was amended or repealed, the second paragraph that originally limited application of the ALI standard was typically left in place.

Today most states have a M'Naghten or modified M'Naghten insanity standard, and most of the rest have an ALI or modified ALI insanity standard. Insanity laws for all 50 states' and federal jurisdictions are listed in the AAPL practice guideline on the insanity defense (American Academy of Psychiatry and the Law 2014). Especially useful, the Practice Guideline provides informative tables that go beyond just the insanity standard for each state.

ABOLITION OF THE INSANITY DEFENSE

Four states no longer have an insanity defense: Idaho, Kansas, Montana, and Utah. In *Clark v. Arizona* (2006) the Supreme Court held that due process does not require any "single canonical formulation of legal insanity" (2722). The

U.S. Supreme Court declined an opportunity to consider the constitutionality of abolishing the insanity decision when it denied *certiorari* in *Delling v. Idaho* (2012). Legal scholars argue that abolition of the insanity defense violates due process, because it disallows nullification of general *mens rea* (see Morse and Bonnie 2013).

THE MEANING OF "WRONGFULNESS"

The cognitive prong of most insanity tests in the United States typically requires that the defendant did not know or appreciate that the act he is accused of was "wrong" or "criminal." The meaning and interpretation of "wrongfulness" or "wrong" varies among states, however (Goldstein and Rotter 1988), and further clarification may be needed to determine whether this is based on a "subjective moral standard" or an "objective moral standard." The subjective moral standard refers to the defendant's subjective belief of whether the criminal act was wrong, whereas the objective moral standard is what the defendant believed to be other people's belief as to whether the act was morally right or wrong (Goldstein and Rotter 1988).

THE BURDEN AND STANDARD OF PROOF

All defendants are presumed to be innocent and sane, until proven otherwise in court. Because of the presumption of innocence, the prosecution has the burden of proving guilt—that is, all elements of the offense charged, including the mental elements—beyond a reasonable doubt (*Davis v. United States* 1895). At the time of Hinckley's acquittal in 1982, the prosecution in federal and most state courts also had the burden of proof that the defendant was not insane. Reforms that followed resulted in the defense assuming the burden of proving insanity in federal and most (75%) state courts (Steadman et al. 1993, 64). Although the standard of proof for the defendant in some states is "preponderance of the evidence," in the District of Columbia and all federal and other state jurisdictions, it is "clear and convincing evidence" (Slovenko 1995).

Involuntary imposition of the insanity defense

The lead landmark case on involuntary imposition of the insanity defense is *Frendak v. United States* decided by the Court of Appeals for the District of Columbia in 1979. Prior cases upheld the trial court's authority to impose an insanity defense on an unwilling defendant. According to *Frendak* a trial judge must first determine whether the defendant waived the insanity defense intelligently and voluntarily before proceeding to impose an insanity defense on an unwilling defendant. The jurisprudence on involuntary imposition of the insanity defense is not settled or uniform. One-third of the jurisdictions allow imposition of the insanity defense on an unwilling defendant. There is considerable variation on who may impose this defense and under what circumstances. Whether the defendant needs to be trial incompetent for involuntary imposition also varies widely (Miller 2002).

DEIFIC DECREE

A defendant, whose act was the fulfillment of a delusional commandment from God, cannot have known the act to have been wrong even if he or she knew the nature and quality of the act and knew that the act violated the law. Known as the *deific decree*, this version of the insanity defense has been adopted by jurisdictions in New York, Washington, and Colorado. The concept includes the moral standard of wrongfulness discussed above.

OTHER MENTAL DEFENSES

Partial responsibility, diminished capacity, and the *mens rea* defense

These three terms—partial responsibility, diminished capacity, and the *mens rea* defense—essentially denote the same principle. Not only for the insanity verdict but for all criminal convictions, the prosecution must prove each element of the offense, including each mental element, beyond a reasonable doubt (*Davis v. United States* 1895; *In re Winship* 1970, 364). If the defendant can defend against a mental element of the crime that the prosecution must prove in order for the defendant to be convicted of the crime, then the defendant can only be convicted of a lesser included crime that does not require this specific mental element. Typically this means reduction of the offense from murder to manslaughter or from first-degree to second-degree murder. Accordingly, the criminal punishment is reduced to correspond with the less serious offense (*Fisher v. United States* 1946).

Diminished capacity

Diminished capacity must be distinguished from the defense of diminished responsibility that originated in Scotland (*HM Adv. v. Dingwall*, 5 Irvine 466, 1867) and was adopted by the British Parliament within the English Homicide Act of 1957. The "diminished capacity" defense was first introduced in the United States by the California Supreme Court in 1949 (Miller 2003), which over several decades developed a remarkable jurisprudence of the doctrine (Bromberg 1979) until the California legislative replaced the diminished capacity with diminished actuality (Nair and Weinstock 2007). Although the classical principle of diminished capacity no longer exists in California, the pioneering jurisprudence that developed the doctrine in California served as a model for other states that would adopt and/or continue to allow a diminished capacity defense.

Heat of passion

Long used to reduce the criminal charge from murder to manslaughter or other less serious offense is the heat of

passion defense. Three elements of this defense that must be proven are as follows: (1) when committing the act, the defendant was under the influence of heat of passion; (2) the sequence of events that led to the heat of passion would have caused a normal person to have acted similarly; and (3) from the provoking event to the act there was no time for the defendant to cool off (Goldstein 1989). Notice that the heat of passion defense does not presuppose a mental illness or defect (Felthous et al. 2001).

The heat of passion defense can negate criminal intent because a defendant who acted from a sudden, incendiary provocation could not at the same time be acting with premeditation. Because intent is an element of the crime of murder to be proven by the prosecution, the prosecution may have the burden of proving that the defendant lacked "heat of passion."

Extreme emotional disturbance

Several states have adopted a broader, formalized defense that can involve some measure of mental disturbance. New York, for example, enacted the "extreme emotional disturbance defense" in 1967 (New York Penal Law 1967). To establish this defense, the defendant must prove that he or she was under an extreme emotional disturbance (EED) when the act was committed. The defendant must as well prove that "there must be a reasonable explanation or excuse, the reasonableness of which is to be determined from the viewpoint of a person in the defendant's situation under the circumstances as the defendant believed them to be" (170). A defendant can put forth the defense if he or she had sustained a "significant mental trauma," according to New York State's highest court. This trauma can erupt inexplicably after remaining dormant, causing the defendant to commit homicide (*People v. Patterson* 1976); thus, in contrast to the classical heat of passion defense, a cooling off period is unnecessary for EED. In contrast to Maine's "heat of passion" defense, EED is a partial affirmative defense wherein the burden is placed on the defendant to prove emotional disturbance by a predominance of the evidence (*People v. Patterson* 1976). In contrast to the "heat of passion" defense, EED does not negate criminal intent, so the prosecution retains the burden of proving intent. The defendant has the burden of proving that the defendant was under the influence of extreme emotional influence when he formed intent.

ALCOHOL, DRUGS, AND CRIMINAL RESPONSIBILITY

In the first half of the eighteenth century Lord Chief Justice Matthew Hale enunciated what has become known as the voluntary intoxication exclusion of the insanity defense. A person who commits an offense while he or she is afflicted with *dementia affectata*, i.e., intoxication, "shall have no privilege by the voluntary contracted madness, but shall have the same judgment as if he were in his right senses" (Hale 1736, 32). Hale went on to describe two situations wherein the effects of an intoxicating substance can lead to exculpation; two potentially exculpatory situations that amount to prevailing law in the United States today (Slovenko 1995). Today the first of these exceptions is known as "involuntary or 'innocent' intoxication," and the second as "settled insanity."

The voluntary consumption of an intoxicating substance, even if causing psychotic symptoms that would meet the functional criteria of insanity, does not qualify as a mental disease or defect for purposes of the insanity defense. The voluntary intoxication exception has prevailed regardless how powerfully psychotomimetic the substance (Slovenko 1995).

Although not qualifying for the insanity defense with complete acquittal, depending on jurisdictional law voluntary intoxication can pertain to a diminished capacity or *mens rea* defense (Singh 1933), or to mitigation at sentencing (e.g., Texas Penal Code, §8.04). Voluntary intoxication can be used as a *mens rea* defense only for the *mens rea* of a specific intent crime: voluntary intoxication is never a defense, even a partial defense, for a general intent crime (Johnson 1994–1995). Montana law does not allow evidence of involuntary intoxication to establish a defendant's diminished capacity (*Montana v. Egelhoff* 1995, 1996) in contrast to the law in most states (Miller 2003). Because of variations in definition and application of diminished responsibility *vis à vis* voluntary intoxication, it behooves the examining psychiatrist to become familiar with the jurisdictional law (American Academy of Psychiatry and the Law 2014).

If consumption was not voluntary and if the resulting mental condition satisfied the functional criteria of the insanity defense, such intoxication could satisfy the insanity defense after all, sometimes termed "temporary insanity" (American Academy of Psychiatry and the Law 2014). Examples of involuntarily induced intoxication or psychosis include taking a mind-altering substance unknowingly or taking a lawfully prescribed medication that results in an unexpected, untoward mental change and the criminal act (American Academy of Psychiatry and the Law 2014). Involuntary intoxication can, according to jurisdictional law, result in complete negation of criminal responsibility because the offender was considered to have been "unconscious" at the time of the offense and incapable of *mens rea* or the formation of criminal intent. As Weinstock (1999) explained, however, the jurisprudence of *mens rea* defenses is "complex, differs from state to state, and is much more complicated than the insanity defense" (14).

Use of alcohol or a drug can result in a complete acquittal based on the insanity defense in jurisdictions that allow a defense of settled insanity. If it can be demonstrated that use of a substance caused or exacerbated psychotic symptoms that persisted after the acute effects of intoxication have passed, the defendant may have a recognized defense of settled insanity (Carter-Yamauchi 1998). The defense of settled insanity has been recognized by several but not all U.S. jurisdictions.

IMPULSE CONTROL DISORDERS

In jurisdictions with an irresistible impulse insanity rule or the ALI insanity standard with its volitional prong, one might expect that a disorder of impulse control (e.g., kleptomania, pyromania, intermittent explosive disorder) could qualify as a mental disorder. There is some evidence that once a pathological condition is recognized in the current edition of the *Diagnostic and Statistical Manual of Mental Disorders* (*DSM*), it can qualify as a mental disorder for the insanity defense, barring further explicit statutory exclusions. After Connecticut courts both allowed (*State v. Lafferty* 1981) and disallowed (*United States v. Torniero* 1984) pathological gambling as an insanity defense, the Connecticut legislature enacted law that excluded pathological gambling for an insanity defense (Conn. Gen. Sta. Ann. §53a-13(c)(2) [West, 1985]). Courts in some jurisdictions have allowed intermittent explosive disorder (e.g., Maryland, *Robey v. State* 1983; New York, *People v. Smith* 1995), whereas other courts have disallowed intermittent explosive disorder (U.S. Military, *United States v. Lewis* 1991).

UNCONSCIOUSNESS, AUTOMATISM, AND SOMNAMBULISM

In order for a criminal act to have been committed, the offender must have not only performed the physical act, but he or she must have done so voluntarily and consciously. Within the criminal law an "act" is "an intentional bodily movement (or intentional inaction) performed in a state of reasonably integrated consciousness" (Morse and Hoffman 2008, 1084–1085). If the *actus reus*, as so defined, was not committed, a crime was not committed. A defense of unconsciousness (*People v. Kelly* 1973) or automatism (Slovenko 1995) is therefore a complete defense.

Sleepwalking can negate the action requirement of a *prima facie* case or provide the "criteria for the affirmative defense of automatism" (Morse and Hoffman 2008). Not having legal authority in the United States, a leading decision by the Supreme Court of Canada may be the best-known sleepwalking case (*R. v. Parks* 1992). Although most cases of criminal acts committed while the defendant was asleep are attributed to sleepwalking (somnambulism), also to be included in the differential are REM sleep disorder and nocturnal dream-derived delusional behavior (Hempel et al. 2003).

POSTTRAUMATIC STRESS DISORDER

Posttraumatic stress disorder (PTSD) has been asserted in various mental defenses including the insanity defense (Jordan et al. 1986), diminished capacity defense (Slovenko 1995), unconsciousness defense, and imperfect self-defense (Berger et al. 2012). It has also been used for mitigation in plea bargaining and sentencing and to ask for a new trial based on failure to investigate for PTSD or ineffective counsel (Slovenko 1995). PTSD has been used successfully for a guilty but insane verdict in Oregon (McGuire and Cleak 2011). Juries have found defendants not guilty by reason of insanity due to PTSD (Appelbaum et al. 1993). The U.S. Supreme Court recognized the importance of a defendant's military history, combat experience, and related mental issues in effectively presenting evidence for mitigation in capital cases (*Porter v. McCollum* 2009). Possible PTSD from service in Operation Iraqi Freedom was the basis for a federal judge to depart downward from the Federal Sentencing Guidelines (*United States v. John Brownfield* 2009). A critical component to the success of a PTSD defense is establishing its clear and direct connection with the criminal act and by support for the traumatic exposure (Berger et al. 2012). The above cases and reviews were based on cases in which diagnostic criteria for PTSD predated *DSM-5* with its substantial changes. Levin et al. discuss the current criteria for PTSD (2014).

PERFECT AND IMPERFECT SELF-DEFENSE AND THE BATTERED WIFE SYNDROME

Psychiatrists do not usually receive referrals when the defense is self-defense, as this defense does not involve a question of abnormal psychology. For an imperfect defense of battered wife or spouse syndrome, however, mental health testimony can be essential. For such cases the consultant should be familiar with the evolution of perfect and imperfect self-defense (see Perkins 1969) as well as the scientific support for the battered wife syndrome.

Where a woman who is beaten repeatedly by her husband, eventually kills him and then claims self-defense, questions can arise such as whether the killing was motivated by revenge, whether she was "against the wall" (self-defense—that can result in acquittal) or could have fled from him, and whether at the time of the killing she believed that she herself was in such imminent danger of being killed or seriously harmed that she had to kill him to avert this danger (imperfect self-defense—that can reduce the grade of the offense). Particularly with recognition of the "battered wife syndrome" in the 1970s, expert testimony became increasingly admissible to establish the mental element of the self-defense defense.

Following *Ibñ-Tamas v. United States* in 1979, some courts found testimony on the battered wife syndrome to be relevant in a self-defense defense against a charge of murder, even as they questioned the reliability of such testimony. In a New Jersey Supreme Court Case (*State v. Kelly* 1984), the court also left to the trial court to decide admissibility based on whether such evidence was sufficiently reliable. (For a different approach, a version of the duress defense taken by the Canadian Supreme Court, see *R. v. Lavellee* 1990.) In most jurisdictions courts admit expert testimony on how domestic violence can influence the behavior and perceptions of battered victims whether they be heterosexual women, nonheterosexual women, adult men, or children (American Academy of Psychiatry and the Law 2014).

PREMEDITATED BY PSYCHOTIC: DELUSIONALLY MOTIVATED OFFENSES

Where the defendant had carefully and purposefully planned and carried out his or her criminal act, but the act was motivated by delusion, the determination of psychosis and its influence on the defendant's behavior can be challenging. Yet in some such cases the defendant can be found to have met criteria for the insanity or other mental illness defense (Felthous et al. 2001). Some schizophrenic offenders show well-organized thought and behavior and yet can be quite dangerous because of delusionally driven behavior (Böker and Häfner 1973).

Once such disorder is diagnosed and the criminal act is thought to have been motivated by delusion, whether or not the defendant's condition satisfied the jurisdictional insanity standard, the defense can hinge on whether the defendant believed his or her act to have been wrong. Here there is the possibility of not only alternative, mutually exclusive motives, delusional and nondelusional, but also multiple "rational" motives for the same act that must be considered in formulating the relationship or lack thereof between delusion and the criminal act.

SUMMARY KEY POINTS

- The origins of criminal responsibility are both theological and philosophical.
- The M'Naghten Rule is the insanity standard for the majority of states and the federal government.
- Important in understanding the meaning of "wrongfulness" in a jurisdictional moral insanity standard is the distinction between subjective and objective moral standard.
- In most jurisdictions the standard of proof for the insanity defense is preponderance of the evidence, with the burden of proof belonging to the defendant.
- Where a mental defense is based on PTSD, of critical importance is the connection between PTSD and the criminal act.
- The imperfect self-defense in homicide cases involving the battered wife syndrome requires that the defendant spouse believed that she was in imminent danger of being killed or seriously harmed.

Post-adjudication evaluations and disposition of insanity acquittees

LI-WEN LEE

INTRODUCTION

Although the insanity defense addresses issues of fairness in the law, the disposition of insanity cases involves consideration of multiple areas of concern, including protection of public safety, provision of appropriate clinical services, and respect for individual liberty interests, all within the constraints of available resources. Historically, insanity acquittees were indefinitely committed to inpatient settings for periods of time longer than the criminal sentence they would have received if they had been found guilty. Beginning in the 1960s, however, mental health advocacy efforts began to yield shorter commitments and deinstitutionalization for the psychiatric inpatient population as a whole. The change similarly impacted the commitment of insanity acquittees, and long-term commitment of defendants found not guilty by reason of insanity (NGRI) could no longer be assumed (Appelbaum 1982). With insanity acquittees returning to the community at a more rapid pace, the public began to perceive the insanity defense as overused (Steadman and Morrissey 1986). The attempted assassination of former President Ronald Reagan by John Hinckley in 1981 and his subsequent use of the insanity defense (*United States v. Hinckley* 1982) added to public perception of the insanity defense as misused and resulted in further public scrutiny of both the insanity defense and management of insanity acquittees (Hans and Slater 1983).

Public perception of the insanity defense as a legal loophole was related to a number of additional factors: mistrust of psychiatric testimony, lack of knowledge about the legal standard for insanity, and the misconceptions about the likely length of confinement subsequent to an insanity acquittal (Hans 1983). Contrary to persistent public perception that the insanity defense is overused (Silver et al. 1994; Perlin 1996), a study of eight states found that the insanity defense is only raised on 1% of felony cases, and when raised, a successful insanity plea occurs in only 26% of attempts (Callahan et al. 1991).

Against this backdrop of misperceptions about the insanity defense and insanity acquittees, the Hinckley case and other high-profile insanity defense cases provided the impetus for insanity defense reform (Borum and Fulero 1999). In some states, a verdict of guilty but mentally ill (GBMI) was added to reduce use of the insanity defense (Steadman and Morrissey 1986), and in a few states (Kansas, Montana, Idaho, and Utah), the insanity defense was abolished altogether.

In those states that retained the insanity defense, insanity defense reform redefined the insanity defense itself and instituted fundamental changes to the post-adjudication process. In many states, procedures were developed to allow the original hearing court to retain jurisdiction over an insanity acquittee's case as he or she moved toward community release. Another example of post-reform change was the provision to allow prosecutor participation in court hearings for community furloughs or release. Conditional release programs were developed to enhance public safety and ensure ongoing treatment (Borum and Fulero 1999).

This chapter focuses on state management of insanity acquittees. The structures of these systems, in the wake of insanity defense reform in the 1980s, reflect a shifting of attention to public safety as a counterbalance to the perception that the insanity defense serves as a mechanism for criminals to avoid punishment. As a result, insanity acquittee management involves numerous, and sometimes competing considerations, including public safety, clinical needs, and limited mental health resources. Clinicians who provide treatment to this patient population may find themselves in a dual role of both treating the patient's illness and addressing the potential dangerousness. They may be required to make disposition decisions based not only on clinical issues but also on public safety considerations. The role of forensic psychiatrists in the disposition of insanity acquittees typically requires some form of evaluation of risk.

Variations on insanity acquittee management systems will be reviewed, including the use of conditional release,

degree of judicial oversight, and use of risk assessment. Descriptions of five state systems will be provided as illustrations of these variations.

OVERVIEW OF STATE MANAGEMENT OF INSANITY ACQUITTEES

After a finding of not guilty by reason of insanity, acquittees may be involuntarily committed for inpatient treatment. Commitment is often to hospitals operated by the state mental health agency, but some states also allow commitment to hospitals operated by the state corrections agency. As an example, Massachusetts allows commitment of insanity acquittees to Bridgewater State Hospital, which is operated by the Department of Corrections (MGL Chapter 123 §16(a) and (b)). Most states, but not all, have commitment procedures for insanity acquittees that are distinct from ordinary civil commitment. The Supreme Court, in *Jones v. United States* (1983) and *Foucha v. Louisiana* (1992), has upheld these commitment procedures for insanity acquittees. *Jones v. U.S.* involved a misdemeanor offense of petit larceny in Washington, DC. After successfully raising the insanity defense, the acquittee was automatically committed to St. Elizabeth's and eventually committed for a period of time exceeding the 1-year maximum penalty associated with his offense. In this case, the Supreme Court upheld the practice of automatic commitment on the grounds that an NGRI finding confirms both that a crime was committed and that mental illness was the cause. The Supreme Court held that an NGRI acquittee could be held in a mental institution until no longer mentally ill or dangerous, and therefore duration of commitment was not related to the length of the hypothetical criminal sentence.

Foucha v. Louisiana concerned the Louisiana statute requiring an NGRI acquittee to be held in the hospital until no longer dangerous, and which placed the burden on the acquittee to show in court that he or she was no longer dangerous. The Supreme Court, in a five-four decision, ruled that an NGRI acquittee could only be committed if still both mentally ill and dangerous.

More recently, in *State v. Klein* (2005), the Washington State Supreme Court reviewed the ongoing retention of an insanity acquittee whose conditional release had been revoked after she resumed using drugs and failed to report to her probation officer. The original offense leading to her status as an insanity acquittee had been related to psychiatric symptoms resulting from drug use, and she was diagnosed with polysubstance dependence and personality disorder, not otherwise specified. The court held that these diagnoses could constitute a mental illness for the purpose of ongoing commitment of an insanity acquittee, and further held that the illness justifying commitment did not need to be the same as that illness forming the basis for the insanity acquittal (Soliman and Resnick 2006). This decision expanded the definition of mental illness required to justify commitment of insanity acquittees in Washington State.

Mental illness and dangerousness are also both required for standard civil commitment, but for insanity acquittees, the seriousness of the instant offense has been found to be an important factor in the length of confinement, sometimes even overshadowing the mental disorder (Silver et al. 1994). In most states, the court that determines NGRI also determines commitment, but two states, Oregon and Connecticut, utilize a review board known as the Psychiatric Security Review Board (PSRB). As another variation on post-adjudication commitment procedures, there are states such as North Carolina where commitment is automatic for insanity acquittees (G.S. §122C-276), at least for an initial period.

In most, but not all, states the state mental health agency must obtain court approval prior to releasing an insanity acquittee into the community (Fitch 2014). In those states where court approval is necessary, opposition to the release from the court or the prosecutor was identified as the most common obstacle to release (Fitch 2014). In the adversarial court system, the prosecution has the opportunity to present evidence and testimony to counter the mental health agency's position that the acquittee is no longer dangerous or mentally ill.

Conditional release for insanity acquittees was introduced in the late 1970s and is utilized to maintain acquittees under court jurisdiction even after hospital discharge. Conditional release provides a least restrictive alternative while maintaining oversight intended to prevent recidivism. In both criminal and civil contexts, conditional release can be a cost-saving step, when compared to further incarceration or hospitalization (Weinstein 2014). Typical conditions of release include stipulations regarding treatment, housing, and supervision. By providing a mechanism for conditional release, rather than allowing for only unconditional release, public safety is enhanced. Most, but not all, states have some form of conditional release (Fitch 2014). In states that utilize a conditional release process, conditional release is viewed as a valuable interim step, during which time there are legal mechanisms by which an insanity acquittee could be removed from the community if safety concerns arise. In the absence of a conditional release system, there is no mandated mechanism to ensure follow-up or monitor outcomes. Clinicians, and courts, are forced to make all-or-nothing release determinations without the benefit of a more gradual transition to the community.

It has been suggested that key features of a successful conditional release program include centralized responsibility, a uniform system of treatment and supervision, and a network of community services (McGreevy et al. 1991), but there are many variations. In some states, the length of conditional release is indeterminate. In contrast, Ohio limits the length of conditional release to the length of the maximum criminal sentence (Callahan and Silver 1998).

Regarding the degree of centralization within state systems, Ohio uses decentralized process where release applications initiated by the treatment team are sent to the presiding judge (Callahan and Silver 1998), while under the

PSRB system, release recommendations historically originated with the PSRB rather than the treaters (Bloom and Buckley 2013). New York has a hybrid structure, with the recommendation to release initiated by the treatment provider but central office review and approval required before the application reaches court (NYCRR part 541).

The decision to release an insanity acquittee to the community entails consideration of several issues. The level of risk to the community must be understood, as well as the conditions of that release that would be necessary to maintain safety. A necessary accompanying consideration is whether the acquittee will comply with those conditions. Douglas (2014) argued that the HCR-20, as a structured professional judgment approach to risk assessment, is useful in informing conditional release decisions. Despite the development of actuarial risk assessment tools and structured professional judgment approaches, recent research regarding the process used to make recommendations for community release has found a great degree of variability. A survey of evaluators in nine states found that there was little uniformity in evaluator conceptualizations of the conditional release process, of how factors should be prioritized in making conditional release determinations, or in the use of structured assessment (Gowensmith et al. 2014).

This issue is not limited to the United States. In Canada, as in the United States, most insanity acquittees are initially hospitalized before returning to the community. A review board determines when an acquittee is ready for release. A study of the Canadian process found that structured risk assessment was not a standard component of information presented to the review board (Crocker et al. 2014). Certain factors influenced the review board significantly: violent behavior and compliance between review board hearings, seriousness of the instant offense, as well as static and dynamic risk factors similar to those found in the HCR-20. Crocker et al. (2014) suggested that the review board might be more cautious in their determinations in the absence of a comprehensive risk assessment.

Oregon

Since 1978, Oregon's system of insanity acquittee management has been based on the Psychiatric Security Review Board (PSRB). Prior to the institution of the PSRB system, there was no form of conditional release. The Oregon PSRB consists of five members of various backgrounds: an attorney, a psychiatrist, a psychologist, an individual familiar with probation and parole, and a lay citizen (Bloom et al. 2000). The PSRB is a centralized mechanism for monitoring insanity acquittees, and the membership reflects the board's role in bridging the mental health and criminal justice perspectives. Under the Oregon system, the trial court determines whether the acquittee remains mentally ill and a substantial danger to others. If determined to no longer suffer from a mental disorder and no longer be dangerous, the acquittee must be released without supervision. For those who are mentally ill or dangerous, the court also determines the maximum sentence possible, had the acquittee been found guilty. The length of this sentence is the maximum length of time the acquittee can be placed under the PSRB, after which time the individual must be discharged or civilly committed. The trial court also determines whether initial placement will be into a forensic hospital or on conditional release. After this point, the trial court is no longer involved in the management of the acquittee, and the PSRB determines movement from the forensic hospital to conditional release. The PSRB also has the authority to revoke conditional release and return an insanity acquittee to a forensic hospital (Bloom et al. 2000).

Data from 1978 to 2011 show that there were 2558 insanity acquittees committed to the PSRB, and 1974 were discharged. The number of insanity acquittees on inpatient status increased from 112 in 1978 to a peak of 405 in 2004, and then decreased to 328 in 2011. The largest category of inpatients in the state psychiatric hospital consisted of insanity acquittees. There was also a large number of acquittees on conditional release, with 400 individuals on this status in 2011 (Bloom and Buckley 2013).

In 2011, statutory modifications to the PSRB system (ORS §161) were prompted by a number of factors, including the increasing number of hospitalized insanity acquittees and fiscal problems, as well as a perception of the PSRB as risk-averse. Insanity acquittees charged with misdemeanors are no longer subject to PSRB oversight and are instead subject to a process similar to civil commitment. In addition, while the PSRB retains jurisdiction of more serious felony insanity acquittees, a parallel system for lower-level felony insanity acquittees was created. These lower-level acquittees are placed under the jurisdiction of the Oregon Health Authority (OHA). OHA created a State Hospital Review Panel (SHRP) to prioritize public safety concerns in rendering conditional release decisions. When acquittees return to the community under conditional release, they are transferred to the PSRB (Bloom and Buckley 2013).

Missouri

In Missouri, the statute concerning insanity acquittees dates to 1963, with additional amendments added in the 1980s and 1990s (Linhorst and Dirks-Linhorst 1997). These amendments increased the focus on public safety through key changes: (1) shifting the burden of proof in the insanity defense onto the defendant, (2) providing for automatic hospitalization of insanity acquittees who committed dangerous offenses, (3) raising release standards for insanity acquittees who committed dangerous offenses, (4) establishing roles for the prosecutor and the Attorney General's office in the release process, (5) requiring court-ordered conditional release, (6) monitoring conditionally released acquittees in the community, and (7) allowing inpatient commitment or community supervision to continue indefinitely (Linhorst 1997).

In 1996, the Missouri legislature tightened the NGRI system by requiring release applications to be filed in the

original court of commitment and mandating notification to victims when release applications are filed. The legislature also added requirements that an acquittee proposed for release (1) not be likely "in the reasonable future to commit another violent crime against another person because of such person's mental illness," (2) understand "the nature of the violent crime committed against another person," (3) knows their behavior was criminal, and (4) is now able to conduct themselves lawfully (Dirks-Linhorst and Kondrat 2012).

In 1997, it was noted that half of long-term public psychiatric hospital beds were occupied by insanity acquittees (Linhorst and Dirks-Linhorst 1997). In 2012, a study of 1130 insanity acquittees concluded that the 1996 legislative amendments may have led to longer hospital stays for all insanity acquittees. Before 1996, insanity acquittees had mean inpatient commitment of 34.3 months prior to reaching conditional release. After 1996, the mean length of hospitalization before conditional release was 75.5 months (Dirks-Linhorst and Kondrat 2012). The 1996 legislative changes resulted in significant changes in practice, and a doubling of the length of stay before conditional release.

New York

New York is an example of a state where the original trial court can retain jurisdiction over post-acquittal process. Oversight of the mental health system is centralized, and conditional release is utilized. In New York, insanity defense reform slightly predated the Hinckley case. The impetus for New York's Insanity Defense Reform Act in 1980 was the highly publicized case of a New York City police officer, Robert Torsney, who shot and killed an unarmed teenager in 1976 (Steadman 1993). His defense claimed that he had suffered from a psychosis associated with epilepsy that caused his behavior (Barrett 2012) as the basis for the insanity defense. As an insanity acquittee, Torsney was then committed to a forensic psychiatric hospital, but no evidence of mental disease could be found. Torsney was recommended for community release less than a year after successfully pursuing the insanity defense. Public reaction to this decision was overwhelmingly negative, with the perception that the insanity defense system had been abused, thus prompting passage of the IDRA.

New York's IDRA resulted in a number of changes (McGreevy et al. 1991). First, the defense was made affirmative, shifting burden of proof from the prosecution to the defense. IDRA also mandates a process to evaluate and determine dangerousness of insanity acquittees, which then determines the degree of court oversight over an insanity acquittee's status and placement. As outlined in statute (CPL §330.20), the post-acquittal process begins with an initial dangerousness determination that dictates subsequent procedures for oversight and privileging. After a finding of nonresponsibility, an individual is evaluated for placement in one of three categories or "tracks": (1) dangerous mental disorder requiring a forensic hospitalization; (2) mentally ill but not dangerous, thus needing civil hospital commitment; or (3) neither dangerous nor suffering from symptoms of mental illness requiring hospitalization, and therefore appropriate for community placement without an initial period of commitment. This initial evaluation is conducted by two psychiatric examiners, but the trial court makes the ultimate determination. Dangerousness determinations require violence risk assessment and are not constrained to the current moment. Case law (*George L.* 1995) established criteria for assessing dangerousness and allows for inclusion of factors such as substance abuse history, need for medication, recency of the instant offense, and the need to prepare for a safe community transition.

Most insanity acquittees are initially found to have a dangerous mental disorder (categorized as Track I) and are placed in forensic psychiatric centers. When patients are deemed no longer dangerous, the treating clinician may apply for transfer to a civil psychiatric center. This application is first submitted to the hospital forensic committee (HFC). If approved by the HFC, the hospital clinical director must then grant approval, and the application is then approved at the central office level before being sent to court. Court hearings are adversarial, and the district attorney's office may oppose the application.

At the civil hospital, when patients are deemed clinically appropriate and safe for community access, they become eligible for increasing levels of privileges before reaching conditional release. Privilege levels off hospital grounds and conditional release status are subject to the same multilevel review and court hearing process as that described for transfer from the forensic to the civil hospital. For conditional release status, a typical order of conditions includes stipulations about compliance with treatment, monitoring by the state mental health agency, approval of place of residence, and prohibitions against substance use. Orders of conditions may be valid for up to 5 years and may be renewed as many times as necessary. Conditionally released patients may be unconditionally discharged after at least 3 years of successful community placement. Unconditional discharge applications are subject to the same application review and approval procedures.

Insanity acquittees found to be mentally ill but not dangerous (Track II) are treated in civil psychiatric centers, without an initial period of commitment to a forensic hospital. Their privilege levels are determined by the hospital in which they reside, without mandated external review, and decisions regarding community release are based on standard civil commitment standards. When released, they are also subject to an order of conditions. Those insanity acquittees who are found during the post-acquittal evaluation process to be neither dangerous nor to have symptoms of mental illness requiring civil commitment (Track III) are able to immediately return to the community, usually with an order of conditions. As with the other two categories of insanity acquittees, they may be unconditionally discharged after the minimum 3 years of community placement.

Insanity acquittees of any track who are in a civil hospital or under conditional release status and who become

dangerous again, as defined by statute, may be recommitted to a forensic hospital. A study of patients recommitted within 10 years after transfer from a forensic facility found that high historical scores on the HCR-20 increased the risk of recommitment almost threefold. Specific risk factors associated with recommitment were prior supervision failure, negative attitude, problems with substance use, relationship problems, and either absent or less serious major mental illness (Green et al. 2014). Recommitment is not the only option; in instances of psychiatric decompensation of community-placed insanity acquittees, voluntary or involuntary civil commitment under mental hygiene law may be pursued.

The statute specifies that transfers, privileges, and releases must be "consistent with the public safety and welfare of the community and the defendant" (CPL §330.20), thus emphasizing the public safety mandate in insanity acquittee management. Centralized oversight provides some degree of statewide uniformity throughout the various facilities, and as described above, progress through the CPL §330.20 process is subject to a multilevel system of review. Perhaps resulting, at least partially, from the complexity of the system, the length of stay for insanity acquittees has increased over time, although the number of new insanity acquittees per year has gradually decreased. In the 1980s, 40% of insanity acquittees were released within 7 years of admission, but in the 1990s, this number decreased to 21%, and by the early 2000s, the number further dropped to only 8%. The number of insanity acquittee admissions dropped from a high of 77 in 1982 to a low of 22 in 2008 (Miraglia and Hall 2011).

South Carolina

Insanity acquittees in South Carolina are automatically hospitalized for a 120-day period. At the end of that time, the criminal court holds a hearing to determine whether continued hospitalization is necessary (S.C. Code §44-17-580). If the acquittee is determined to require further hospitalization, the acquittee remains in the hospital until the state mental health agency notifies the court that confinement is no longer necessary, at which time, the court will hold a release hearing. The original trial court may hold jurisdiction for a period of time equivalent to the maximum sentence for the instant offense, after which standard civil commitment procedures are followed. Considerations regarding the necessity of further hospitalization include sufficiency of insight, capacity to make treatment decisions, or likelihood of serious harm to self or others, but the statute does not speak to the use of therapeutic passes or to the conditions of confinement (Young et al. 2002). In the absence of statutory guidelines for the conditions of confinement, the South Carolina Department of Mental Health operated a seven-level insanity acquittee treatment program called the Allan Project, designed to offer increasing independence and decreasing supervision with each successive level (*State v. Hudson* 1999). Progression through the seven levels was a clinical determination made by the treatment team, and patients on higher levels could be granted passes for work or social activities in the community (Young et al. 2002).

South Carolina is another example of a high-profile case impacting the mental health system's autonomy in managing insanity acquittees. In this instance, Ui Sun Hudson attacked three children with a pair of scissors in 1995 and caused serious injury. She was found NGRI and hospitalized as statutorily required. The hearing regarding the need for further hospitalization did not occur until 18 months later, despite the 120-day time frame specified in statute. During this time, Hudson reached level four of the seven-level program, and the hospital granted her gradually increasing periods of unsupervised time in the community, including travel to employment. At her hearing, the attorney general and the judge expressed concern about unsupervised access to the community despite the lack of any adverse incidents. The judge found Hudson "in need of further hospitalization." Although the judge agreed to allow her to remain on her current level of privileges, he also ordered the hospital to obtain court approval prior to allowing her to advance to the next level or attain more privileges. The South Carolina attorney general (AG) remained unsatisfied with this ruling, and as a result of the AG's legal challenge, a consent order specified that the South Carolina Department of Mental Health (DMH) would obtain court approval prior to allowing unsupervised leave in any form from hospital grounds (*State v. Hudson* 1999).

Despite the decree, the AG appealed the original ruling. The South Carolina Court of Appeals determined that a committed NGRI patient could not have unsupervised leave from the hospital. As a result of this ruling, NGRI patients in the upper levels of the seven-level program and residing in the community under outpatient monitoring were abruptly returned to the hospital until court hearings could be scheduled, a process that took over a year (Young et al. 2002).

Maryland

Insanity acquittees in Maryland may be committed to the state Department of Health and Mental Hygiene or may be released to the community, either with or without conditions. As in other states, release from a secure facility may be either through conditional release or release without conditions, but in either situation, a formal hearing regarding dangerousness is required. Acquittees may petition for release annually, though the state may apply for release at any point in time (Md. Code Ann. 2006). Conditional release plans are reviewed by the state Community Forensic Aftercare Program (CFAP), and conditional release orders are usually 5 years in length but may be shorter or longer (Marshall et al. 2014). Acquittees on conditional release status are monitored by CFAP social workers, with information on the acquittee's mental status, compliance, substance use, and community functioning provided by caregivers, treatment providers, and family. Insanity acquittees in need of return to inpatient care can be voluntarily readmitted,

but if the conditions of release have been violated, the court may revoke conditional release status.

Voluntarily readmitted insanity acquittees were found to have fewer arrests and fewer instances of treatment noncompliance than those insanity acquittees who were involuntarily readmitted. Those acquittees who were not readmitted at all had longer community duration prior to any psychiatric readmissions and fewer community psychiatric admissions. An interesting finding of Maryland's program was that acquittees residing with family members were more likely to be involuntarily readmitted than those living in community or structured residences, possibly because family members were more likely to notice problems or because the family was a destabilizing, rather than supportive, factor (Marshall et al. 2014).

PUBLIC SAFETY

Data published regarding conditional release programs generally show low re-arrest rates for insanity acquittees. Wiederanders et al. (1997) examined conditional release data from New York, Oregon, and California and found felony re-arrest rates ranging from 2.2% to 2.8% per year, and annual re-hospitalization rates from 14.5% to 20.4%. A 2011 study on New York insanity acquittees estimated that 2% of women and 14% of men were re-arrested within 2 years of release, with most re-arrests occurring within the first 5 years of release. Contrasted with the re-arrest rate from state prison, 42% for women and 56% for men, the re-arrest data for insanity acquittees were found to be favorable (Miraglia and Hall 2011). These statistics suggest that insanity acquittee management systems, as compared with incarceration, have been effective in reducing risk to the community.

With regard to risk factors, the New York study found that the factors associated with increased risk for any re-arrest were male gender, a diagnosis of antisocial personality disorder, and being in treatment for less than 2 years. The only predictor variables for re-arrest for violence were found to be the number of prior arrests for violence, age at release, and gender, as no women in this sample were re-arrested for violence in the New York study (Miraglia and Hall 2011). McDermott et al., in a 2008 study of insanity acquittees at Napa State Hospital in California, attempted to elucidate how clinicians make release decisions and found that three concerns appeared to be key considerations: responsiveness to and compliance with treatment, substance use, and risk of violence.

As mentioned earlier in this chapter, two responses to calls for insanity defense reform were to introduce the GBMI verdict to reduce the number of insanity acquittals and to abolish the insanity defense altogether. The Michigan experience with GBMI found that rather than decreasing the number of insanity acquittals, addition of GBMI resulted in relatively stable numbers of new insanity acquittees with an additional number of defendants found GBMI (Steadman 1986). A criticism of the GBMI verdict is that it may create expectations that a defendant found GBMI will receive specialized treatment, while in fact a finding of GBMI does not typically provide opportunities for treatment beyond what is ordinarily provided to other convicted state inmates.

In Montana, where the insanity defense was abolished, the impact of mental illness on criminal responsibility was not eliminated from consideration in the judicial system (Buitendorp 1996). Evidence that would have previously been submitted to support an insanity defense was instead used to support findings of incompetence to stand trial, *mens rea* considerations, and sentencing. The net effect of the redirected evidence regarding mental illness was to essentially allow a version of the insanity defense to continue despite abolition. One key difference with states allowing the insanity defense, however, is the post-adjudication process. Incompetence to stand trial could lead to dismissal of the charges, and hospitalization after that juncture was not necessarily the case. This raised the potential for a class of individuals who would previously have been committed for treatment but were instead able to avoid treatment.

Both the Michigan and Montana examples of attempting to avoid the insanity defense result in the possibility that defendants whose behavior was influenced by mental illness actually received less treatment than those defendants in other states who are able to receive the insanity defense. Given the conservative nature of many state conditional release programs and hospital services for insanity acquittees, this may have the unintended consequence of diminishing public safety rather than enhancing it.

USE OF LIMITED RESOURCES

In 1986, Steadman and Morrissey commented that insanity defense reforms resulted in a disproportionate investment of resources drawn from an already burdened mental health system. More recent studies have found that conclusion to remain valid. Even as the number of state hospital beds has steadily decreased from 500,000 in 1950 to 30,000 in 2010 (NASMHPD 2014), the percentage of state hospital expenditures on forensic services for insanity acquittees and competency restoration has increased over time. States have noted increasing numbers of forensic admissions to state psychiatric hospitals (Manderscheid et al. 2009). In 1983, state psychiatric hospitals expended 7.6% of their funds on forensic services, but by 2012, that figure had risen to 36%. In the setting of dramatically reduced state hospital bed availability, the utilization of inpatient beds for insanity acquittees can represent a significant use of resources. The extended length of stay of many insanity acquittees is an additional factor (NASMHPD 2012). On the other hand, as discussed earlier, research has found that insanity acquittee management systems can reduce re-offense rates. There are benefits that can be more elusive in terms of determining monetary value, including improved clinical outcomes and prevention of harm by avoidance of future offenses.

SUMMARY

Treatment and management of insanity acquittees must address clinical needs, but considerations for civil liberties are inevitably tied to issues of public safety and mental health resources. This is a delicate balance that can be tipped by a single, high-profile adverse event, as has been demonstrated in numerous states.

State management of insanity acquittees, when less centralized, can offer treatment providers greater flexibility to use clinical judgment, but centralized management offers the opportunity for more consistency in application of the relevant standards, and for assessing practice and tracking outcomes. Highly tiered review processes may be prone to more conservative decision making. Ultimately, the ideal would be to develop an insanity acquittee management system where risk assessment practices can be relevant for both public safety considerations as well as treatment planning.

SUMMARY KEY POINTS

- A finding of not guilty by reason of insanity typically triggers a process of assessment and review in which risk considerations impact clinical management options.
- States vary in the structure of insanity acquittee management in numerous ways, such as the process by which initial commitment is determined, and the complexity of mandatory review, availability of conditional release. Most states require court approval prior to community release.
- Release determinations in most jurisdictions involve assessment beyond current clinical status and behavioral stability. Additional considerations include understanding the level of risk to the community, the components of a release plan that would be necessary to maintain safety, and the likelihood of compliance to such a plan.
- Use of risk assessment tools is also variable but may be helpful in structuring assessments regarding readiness for community release or other related steps in insanity acquittee management.

Presentencing evaluations

ALAN R. FELTHOUS

PRESENTENCING EVALUATIONS

Presentencing psychiatric evaluations can be requested by the defense or prosecuting attorney. The purpose of these evaluations is to assist the judge or jury in answering one or more of the following questions following criminal conviction: (1) Is the defendant competent to be sentenced? (Miller 2003, 203–204), (2) What treatment recommendations, if any, should be considered by the sentencing authority? and (3) How severe or lenient should the punishment be? (Felthous 1989). Pre-capital sentencing evaluations are addressed in Chapter 11 and so will not be discussed here.

In order to place the psychiatrist's role in sentencing into context, this chapter begins with a brief historical review of criminal punishment, followed by a discussion of the four purposes of punishment and the psychiatrist's role within each of these penal purposes. Finally the presentencing report itself will be described. This discussion will address the three main questions that concern psychiatric presentencing evaluations: competence, treatment recommendations, and mitigation.

Crimes, offenses against the king, were eventually defined as offenses "against the community at large." The criminal justice system regulated procedures for investigation, indictment, prosecution, and punishment for those convicted (Garner 1999, 381). Those convicted of a crime were subject to criminal sentencing, i.e., the imposition of a punishment. A court or jury pronounced and imposed the sentence.

As torture in the Middle Ages faded into disfavor, countries such as England, France, and tsarist Russia transported criminals to far-off places (Barnes 1930; Barnes and Teeters 1959). From 1597 until 1776 England transported criminals to the American colonies (Barnes and Teeters, 1959; Smith 1997). After 1776 and American independence, the English transported felons to Australia.

In the American colonies all punishment was corporal (Mattick 1974) and incarceration was not much used (Derschowitz 1978). Offenders who committed serious offenses were whipped, branded, mutilated, and put to death. Perpetrators of minor offenses were punished by public humiliation such as being subjected to the pillory, stocks, and dunking stool (Barnes and Teeters, 1959).

IMPRISONMENT

Meanwhile, by the sixteenth century in several European countries, bondage, meaning forced labor with restrictions in freedom, became an increasingly used alternative to the spectacle of the scaffold and physical punishments such as flogging (Spierenburg 1995). Upon breaking away from England, Americans also repudiated its severe punishments including execution for a variety of offenses. By the same token reducing such severe punishments was thought to better ensure conviction, and the increased certainty of punishment, it was hoped, would reduce crime (Rothman 1995). By the end of the seventeenth century, prisons intended for confinement began to replace work prisons (Spierenburg 1995). As execution became less available in the United States, this young country turned to long term imprisonment as the predominant punishment for most serious offenses (Rotman 1995).

CLASSIFICATION

As the penological goal of rehabilitation took hold, classification became a common practice in progressive correctional systems. Some prison units would be designed almost exclusively for security, maximum security, and eventually even supermaximum security. Other facilities devoted more resources toward rehabilitative programming. By the early twentieth century, state correctional departments began to include special institutions for the mentally ill or "defective delinquents," at Napanoch, New York, in 1921 and at Bridgewater, Massachusetts, in 1922 (Rotman 1995). Classification today typically takes place after sentencing and within the prison system. It has and can, however, occur in lieu of, or as part of, the sentencing process.

The four penalogical purposes of criminal punishment are retribution, deterrence, incapacitation, and

rehabilitation. Expiation, of ecclesiastical and historical interest (Gardiner 1958), is no longer a consideration. Retribution is nonutilitarian, whereas each of the other purposes is intended to reduce or prevent crime. In *Traltato dei Delitti e Pelle Pene* (Essay on Crimes and Punishment) published in 1764, the Italian criminologist Cesare Beccaria first described the principles of *retributivism*. He argued against secret proceedings and torture and in favor of a humanitarian and a consistent legal system in which the punishment fit the crime (Barnes 1930). According to the classical school, punishment should be proportional to the crime for all offenders yet also humane and fair (Robinson 1922). Immanuel Kant (1965) asserted that society had a "categorical imperative to impose punishment fitting the crime." The ideal of *just taliones* was to be proportionate, not equivalent to the crime (p. 132).

Herbert Morris (1968) described punishment as a natural and inalienable right that respects an individual as a person. Premised on a person's capacity to freely choose his actions, including violation of society's most fundamental rules, proportionate punishment respects the person's choices *per se* as well as his choice in effect in deciding the sanctioning consequences of his offense conduct. This contrasts with a purely therapeutic or rehabilitative model that could result in tyrannical control over the individual with disregard of his freedom of choice of predictable outcomes. Nonetheless, the retributionists' punitive model is inappropriate for the mentally ill who because of their illness lack freedom of choice; respect for their personhood is better satisfied with the treatment model (Morris 1968), this exception to culpability falling within a contemporary retributionist system.

Culpability pertains to both adjudication of guilt and severity of punishment. Mental factors that might not have risen to the level to amount to a successful mental defense can nonetheless pertain to the comparative proportionality of punishment. The forensic psychiatrist can in effect assist the court in determining the appropriateness of retribution and setting the severity of punishment by conducting a presentencing evaluation that is similar to that for criminal responsibility (Appelbaum and Zaitchik 1995). Rarely, the discovery of new evidence in support of an insanity defense could lead to a new trial (*State v. King* 1989), but more typically the presentence evaluation can result in mitigation of sentence, leaving the original conviction in place. The presentencing evaluation can assess a broader range of factors than a responsibility evaluation (Appelbaum and Zaitchik 1995). As capital sentencing hearings especially welcome wide-ranging considerations addressed in Chapter 11, here the focus is on factors allowed in noncapital cases, with the realization that some factors may be equally relevant and admissible to both capital and noncapital sentencing.

Deterrence is a utilitarian theory of punishment wherein the punishment itself is intended to deter, prevent, or reduce the risk of future criminal behavior (Felthous 2007). Plato, the earliest philosopher to support primary and secondary deterrence as the justifying purpose of criminal punishment, maintained that offenders should not be punished because of their crimes but to prevent them and others from engaging in future criminal acts (Plato 2005, 196–197). With primary or specific deterrence, the individual offender should resist future criminal behavior because of the known penal consequences (Stetlerand and Goldstein 2003). With secondary or general deterrence, others in society should learn from the offender's consequential example and avoid making the same criminal mistake. Plato's concept of exemplary deterrence became a common purpose of criminal punishment in ancient and medieval systems of social control (Peters 1995). Consistent with this purpose, punishment was carried out as a public spectacle.

The psychiatric presentencing evaluation can relevantly address how the defendant's mental condition will affect the likelihood that punishment will deter his or her criminal conduct (Appelbaum and Zaitchik 1995). This can be a double-edged sword, however, in terms of sentencing severity. Although decreased likelihood of deterrence diminishes the justification for severe punishment, it could increase the justification for incapacitation resulting in longer, not shorter sentencing.

The separate question of general deterrence raises the possibility that severe punishment will serve to deter most individuals, but not necessarily individuals who themselves are mentally disordered (Appelbaum and Zaitchik 1995). The extent to which punishment of mentally disordered individuals deters others from criminal acts and the extent to which courts consider general deterrence when sentencing mentally disordered defendants are empirical questions with unknown answers. Appelbaum and Zaitchik (1995) suggest that in cases wherein the goal of sentencing is deterrence, the evaluator can assess the extent to which the defendant's mental condition would motivate future criminal conduct and the likelihood that deterrence would be lessened.

Just as the penological goal of deterrence can interact with incapacitation, so can it interact with rehabilitation. Diminished capacity for deterrence can be due not just to the impairment of the mental condition but to its resistance to treatment. Where the lack of deterrence is due to mental illness, but mental illness is improved with treatment, the defendant may regain the capacity to be deterred by punishment, even when imposed as a result of a criminal act committed while he or she was mentally disordered. Thus, if the evaluator addresses deterrence that could enhance punishment by contributing to the need to incapacitate, the evaluator should also attempt to address the alternative purpose of rehabilitation and the potential to be deterred by punishment by virtue of successful treatment. Although in many cases treatment can be provided within the correctional system, amenability to treatment and therefore deterrence ought not to be justification for a penal rather than a therapeutic disposition. Rather, where the defendant has already been convicted, treatable mental disorders with resultant deterrence ought to favor leniency in sentencing.

Incapacitation is the attempt to render the offender incapable of committing future crimes by making recidivism

nearly physically impossible, at least during the period of incapacitation. Obviously execution is the most extreme and final form of incapacitation. Imprisonment always serves the purpose of incapacitation because at least while the offender is incarcerated he or she cannot victimize others in society.

In addressing whether, because of the risk of violence or recidivism, the defendant should be incapacitated, the court may turn to the psychiatrist's presentencing report. The court may be more likely to impose a lengthy prison sentence if the presentencing report suggests that the defendant is at high risk for reoffending (*Idaho v. Snow* 1991), or is not amenable to treatment and has a criminal history (*State v. Pryor* 1990; *State v. McNallie* 1994), whereas a mental condition that somehow reduces the risk of recidivism could favor leniency (*United States v. Studley* 1990). Thus, the presentencing evaluation is most relevant to the penological goal of incapacitation when dangerousness and criminal recidivism are addressed (Appelbaum and Zaitchik 1995).

More accurate, and in keeping with American Psychiatric Association (APA) recommendations, than declaring whether or not a defendant is dangerous, the evaluator can identify those factors that increase the risk of violent or criminal behavior (APA 1984). The presentencing report can also usefully identify protective factors that reduce the risk of violence or recidivism. Importantly the report can as well identify those factors that can reduce the intensity or likelihood of predisposing factors (Appelbaum and Zaitchik 1995). For example, if bipolar disorder increases the risk of assault when the patient becomes manic, this risk can be reduced by factors that support the defendant's compliance in taking an efficacious mood stabilizer.

The third utilitarian and fourth theoretical purpose of punishment is *rehabilitation*. Although Plato is most closely associated with deterrence, this early utilitarian also wrote in favor of rehabilitation. For those whose criminal propensities are amenable to reform, such as where the criminal acts result from ignorance, the proper intervention is correction and instruction (Peters 1995; Plato 2005). Cesar Lombroso, the Italian physician and anthropologist who founded the Italian school of criminology, argued that punishment should be determined by the nature of the offender, not the type of crime committed. In the late nineteenth century he published a pamphlet that catalyzed the rehabilitation movement as a major force in penology (Robinson 1922). An offender who steals for food could, for example, be taught a marketable skill so he or she can earn a living. Lombroso was not an absolutist, however, and would reserve incapacitation for offenders who were considered unchangeable by efforts at rehabilitation.

Rehabilitation can involve much more than simply psychiatric diagnosis and treatment. It can involve job training, for example, and successful job application. At least the evaluating psychiatrist should address mental conditions that can interfere with rehabilitation efforts and increase the risk of recidivism. The presentence report will be most useful if it identifies available treatment programs both inside and outside the correctional system (Appelbaum and Zaitchik 1995). The sentencing court may specify treatment measures as conditions of probation enforceable by revocation of probation and imprisonment when such measures are not followed by the mentally disordered offender (*United States v. Gallo* 1994).

STATUTES

Several states (e.g., California [Pre-sentence 1965], Kansas [Davis et al. 1971; Kan. Sentencing Code, 1969], Massachusetts [Mass 1970], Maryland [Smith 1976], New Jersey [Smith 1976], and North Carolina [Smith 1976]), and large metropolitan areas (e.g., Baltimore, Chicago, Cleveland, Detroit, New York City, Philadelphia, Pittsburgh, and Washington, DC [Felthous 1989]) enacted statutory provisions for psychiatric presentencing examinations. The goal of the Kansas State Reception and Diagnostic Center (KRDC), opened in 1961, was to promote effective rehabilitation of male felons (Davis et al. 1971). After conviction of a felony and sentencing, the defendant underwent a thorough multidisciplinary mental evaluation at KRDC. North Carolina's 1967 statutory enactment (Smith 1976; Jones 1969) served a similar purpose to that of Kansas. By this presentencing statute the judge could assign a multidisciplinary study group to gather information for the judge to use in sentencing (N.C. Gen. Stat. 1977).

This brief synopsis and the historical evolution of sentencing in the United States is intended to provide the psychiatrist with useful context for the specific task of conducting presentencing evaluations.

THE RELEVANCE OF PRESENTENCING EVALUATIONS TO THE PURPOSES OF PUNISHMENT

One might expect that retributivism would hold no place for presentence evaluations, because the severity of the punishment must correspond to the severity of the criminal offense, at least proportionately so. Modern retributivism, however, allows for a defendant's mental condition to be considered in assignment of criminal responsibility (Gray 2010; Johnston 2013, 2014) and in determining the nature and severity of punishment. Two retributive rationales support judicial authority in adjusting a defendant's sentence to meet his treatment needs or reduce the hardship of punishment that is caused by his mental disorder: to avoid violating human dignity and to support the principle of equal impact (Johnston 2014).

Harsh punishment, including deprivation of certain rights, is acceptable; inhumane punishment is not. Corporal punishment once acceptable is no longer because it is considered to be inhumane. Retributivist punishment is "[p]remised upon respect for the moral dignity and personhood of the offender" (Johnston 2014, 644). Thus, violation of human dignity is incompatible with retributivism. Like corporal punishment, any punishment that is intended to profoundly disturb a person's mental health is impermissibly

inhumane. Johnston argues that prison sentencing, without allowance for a mentally disordered offender's reasonably foreseeable and serious vulnerabilities, results in an inhumane violation of his dignity. Therefore, the sentencing judge should be authorized to modify confinement conditions so as to be proportionately punitive yet not morally intolerable.

A related concept for considering the defendant's vulnerability to adverse effects of criminal punishment because of mental disorder is "the principle of equal impact" (Johnston 2013). Most legal scholars maintain that the just desserts theory of retributivism requires an objective standard (Gray 2010) that relates the punishment to the defendant's culpability from the nature and severity of the criminal act. Some commentators in contrast recognize that a given sanction such as incarceration can have a greater impact on defendants with vulnerabilities such as mental illness (Gray 2010; Johnston 2013). They recommend that the assessment of punishment take into account its differential, greater effect on such defendants (Gray 2010; Johnston 2013), a consideration referred to as the "equal impact principle." "The equal impact principle thus acknowledges the foreseeable, typical, and serious side-effects that certain penalties hold for vulnerable populations and seeks to adjust ordered sanctions so that members of vulnerable classes receive penalties of roughly equivalent severity as non-vulnerable individuals" (Johnston 2014, 646). Importantly, application of the equal impact principle in sentencing does not mean a reduction in punishment. Application realizes the principle of proportionality of retributivism and accordingly equalizes "the severity of penalties imposed on equally blameworthy offenders" (Johnston 2014, 646).

How these considerations are operationalized and put into sentencing practice is not clearly delineated. Courts have reduced or altered their customary sentencing out of concern for the harmful effect on vulnerable defendants. This has been justified by considering the mental disorder to have lessened the defendant's mental responsibility for the crime, even though such may not have resulted in a successful mental illness or defect defense. While accurate prediction of impact for mentally vulnerable defendants may be elusive, the forensic evaluation may be able to comment on recognized vulnerabilities and likelihood of improvement or deterioration under various sentencing conditions. Above all, the presentencing report should clearly state the defendant's treatment needs, including hospitalization if this level of care is required.

COMPETENCY TO BE SENTENCED

A presentencing evaluation assessment for competency to be sentenced does not fit well within the four theories of punishment, as this has more to do with procedural fairness and due process than punishment *per se* and so is more closely related to the criminal competencies discussed in Chapter 12. In some countries, e.g., Germany (Felthous et al. 2000), the central concern is the defendant's capacity to *serve* sentence in a prison setting.

U.S. jurisdictions differ in which standard for competence to be sentenced applies to noncapital sentencing. Some require that the defendant understand why he or she is being sentenced, whereas others apply the same standard as *Dusky* for trial competence (*Dusky v. United States*, 1960). Some but not all jurisdictions afford the defendant a right of allocution (Johnston EL, November 18, 2014, personal communication). According to the Ninth Circuit, a trial court is required to order a competency hearing if there is "reasonable cause to believe that the defendant may presently be suffering from a mental disease or defect rendering him mentally incompetent" (*United States v. Dreyer* 2012, 808). The threshold question was whether evidence would cause a "reasonable judge" to "experience genuine doubt" about the defendant's competence (*United States v. Dreyer* 2012, 808, citing *United States v. Mark* 2008, 814).

The question is whether the convicted defendant can protect his own rights throughout the sentencing procedure. The defendant must be able to provide relevant information to the person who is preparing his or her presentencing report. In order to ensure that information, conclusions, and recommendations are accurate, the defendant must be able to object when needed (Miller 2003). Allocution, the capacity to speak on one's own behalf during sentencing, has been considered an "elementary right" in assisting one's own defense (Peterson and Martinez 2014, 394–395; *United States v. Dreyer* 2012). Competency to be sentenced requires that the defendant know that he or she was convicted of a crime, reasons for the conviction, possible penalties, and why the court can sentence him or her to an appropriate punishment (Miller 2003).

Although seldom used in the United States, a functional approach has also been applied by the sentencing authority addressing whether the defendant has the capacity "to cope safely in a correctional setting" (Appelbaum and Zaitchik 1995, 681). A court might well consider whether imprisonment will aggravate the defendant's mental disorder (Sadoff 1988), increase the risk of suicide, or cause decompensation (Felthous 2008). A court's willingness to reduce the length of imprisonment because the defendant is mentally retarded may represent mitigation due to a mental condition (see below) more than a finding of incompetence, although the defendant's limited capacity to cope can be a consideration. (See, for example, *Illinois v. Watters* 1992.) In general sentencing a defendant with serious mental illness or mental retardation does not result in a finding of incompetence to be sentenced (Felthous 2008).

SEVERITY OF PUNISHMENT

Within the relevant sentencing guidelines, the court must decide where on the scale of leniency to severity a particular defendant should be sentenced. For this the court will consider various factors such as how heinous the crime was and how responsible the defendant was for his or her behavior.

Both of these factors contribute to the amount of moral turpitude attached to the defendant because of his or her crime and what corresponding degree of punishment would be most appropriate. Traditionally, when *mens rea* was shaped by ecclesiastical law, it was the free but errant exercise of the metaphysically free will that rendered the defendant criminally responsible (Felthous 2008). Through centuries of English common law, leading jurists maintained that it was the lack of rational thinking that crippled the will's capacity to function properly, so irrationality became a core defect to be identified by successive insanity tests.

According to the APA's Task Force on Sentencing (1984), psychiatrists should not make recommendations for disposition; rather they should strive for beneficence and nonmalfeasance in their recommendations. The psychiatrist who conducts a presentencing evaluation will therefore not contribute to the severity question by recommending for or against imprisonment. By conducting a thorough evaluation and full disclosure, his or her report can support public protection without a specific recommendation for imprisonment. The psychiatrist can comment on factors that affect the risk of violent behavior without attempting an accurate prediction.

Although these guidelines do not mention the will, i.e., the intentional, decisional faculty, or the question of criminal responsibility and moral turpitude, courts will consider these qualities when sentencing. Courts can be expected to apply presentencing evaluations to aspects of criminal responsibility, even though the defendant was already adjudicated guilty and therefore criminally responsible for the offense and even if the presentencing report did not address criminal responsibility in the broader sense, often framed as mitigating and aggravating factors. Indeed the hearing in question may be known as a "mitigation hearing."

MITIGATION

When psychiatric evidence is presented at the sentencing hearing, it is often referred to as a mitigation evidence or report. Here we consider several conditions for which psychiatric assessment may be requested before considering whether such conditions should result in mitigation or a reduced or more lenient sentence.

INTELLECTUAL DISABILITY

Several court decisions resulted in mitigation with reduced prison sentence due to mental retardation (now termed "intellectual disability" according to the *Diagnostic and Statistical Manual of Mental Disorders*, 5th edition (*DSM-5*, APA 2013). *Illinois v. Watters* (1992) was cited above. In *United States v. Chambers* (1995), the sentence of a borderline mentally retarded defendant was reduced from 188 months, the federal guideline minimum, to just 21 months based on "extraordinary family circumstances" and "diminished capacity" allowed by Federal Sentencing Guideline 5K2.13. In *United States v. Lewinson* (1993) the Ninth Circuit held that a mental disorder need not be a "'severe' impairment." Section 5K2.13 of the Federal Sentencing Guidelines (18 U.S.C. §1341) allows a downward departure from the Sentencing Guidelines if the mental disorder "significantly reduced [the] mental capacity [of the defendant] without qualification as to the nature or cause of the reduced capacity/except with respect to voluntary drug use" (p. 1006). Mental retardation may evoke a merciful response or effort to reduce prison time because of poor coping ability. The *Lewinson* case, however, clearly illustrates the concern about the offender's reduced criminal responsibility, termed "diminished culpability" (p. 1007) even if already found sufficiently responsible to be adjudicated guilty of the offense.

VOLUNTARY INTOXICATION

Evidence of voluntary intoxication is admissible at capital sentencing hearings for the purpose of mitigations. For noncapital offenders, in contrast, voluntary intoxication is typically mentioned in sentencing guidelines in order to limit or exclude its consideration. Marlowe, Lambert, and Thompson (1999) reviewed law in all U.S. jurisdictions and determined that jurisdictions follow one of the following ways in dealing with evidence of intoxication: (1) prohibition of such evidence; (2) admission of such evidence provided that it satisfies a substantive standard that is similar to wording in the insanity defense; (3) implicit inclusion in a "catch-all" sentencing provision; and (4) no published precedential guidance, leaving the matter to the trial courts.

The substantive standard inclusion provision varies widely among the few jurisdictions that follow this approach. In Arizona the standard is essentially its state's statutory insanity standard, i.e., intoxication must have "significantly reduced" the defendant's "capacity to appreciate the wrongfulness of the conduct or to conform it to the requirements of the law" (Ariz. Rev. Stat. §13-702). More broadly cast, in California and North Carolina the defendant must have "suffered" from a mental condition that "would [have] reduced his or her culpability (Cal. Rules of Court, Rule 423; N.C. Gen Stat. §15a-1340.16)" (Marlowe et al. 1999). In some extreme cases voluntary intoxication can pertain to "criminal responsibility" for purposes of punishment where it was not allowed as a defense against the criminal offense. For example in Texas where evidence supports temporary insanity caused by intoxication, such evidence may be introduced to mitigate the penalty and the court can instruct the jury accordingly (Texas Penal Code, Section 8.04).

A "catch-all" sentencing provision may, like that of Illinois law for example, permit evidence of "any other factors" that may be relevant to mitigation of punishment (Ill. Ann. Stat., Ch 730 §515-5.3.1). Marlowe et al. (1999) note that intoxication may be allowed into evidence without showing that the state of intoxication was actually connected to the criminal act. They caution against using intoxication that is unrelated to the offense, however, because it could

be excluded as misleading or irrelevant, or if admitted, be considered as unconvincing by the fact finder.

Rehabilitation for an alcohol or drug use disorder can be a double-edged sword. Some courts have favored lighter sentences if the rehabilitation effort appeared to have been successful (*People v. Chen* 1991; *People v. Smith* 1995) and others have not supported leniency where rehabilitation failed (*State v. Wielkiewicz* 1993). In some federal cases wherein the defendant's effective use of rehabilitation was considered exceptional, it can serve as a basis for downward departure from sentencing guidelines (*United States v. Harrington* 1992; *United States v. Sally* 1997). Otherwise federal sentencing guidelines do not permit voluntary intoxication for downward departure (Marlowe et al. 1999, 204, note 4, citing *U.S. Sentencing Guidelines* §5K2.13). North Carolina exceptionally permits involvement in a rehabilitation program for mitigation (N.C. Gen. Stat. §15a-1340.16[E]). Without explicitly mentioning intoxication or substance abuse, some statutes consider "rehabilitative needs" to be relevant to sentencing (Marlowe et al. 1999).

Slobogin et al. (2009) note that state statutes that require proof of an aggravating or mitigating factor can result in sentencing at wide variance from the presumptive sentence. Arizona judges can increase the sentence by 25% or decrease it by 50% if requisite aggravating or mitigating factors are proven (Arizona R.S., §§13-502, 13-7-1, 13-7-2).

SENTENCING GUIDELINES

Federal and state sentencing guidelines set parameters and recommendations for judicial sentencing. Mandatory sentencing requirements must be based on facts found by the jury. Advisory guidelines, on the other hand, do not depend on such facts. Thus, the U.S. Supreme Court in *United States v. Booker* held in 2005 that the Federal Sentencing Guidelines were unconstitutional, i.e., in violation of the defendant's Sixth Amendment right to a jury trial, to the extent that these guidelines mandated enhanced sentences based upon facts that had not been found by the jury. In an earlier decision the Supreme Court had found similar state sentencing guidelines to be unconstitutional (*Blakely v. Washington* 2004).

Most of the seven general federal sentencing factors concern moral aspects of punishment and which sentencing options are available (18 U.S.C.A. §3553(a) [main ed. and supp.] 2004); most would not pertain to the psychiatric presentencing evaluation. The most relevant of these are the first two: the psychiatric evaluation includes the defendant's history and personal characteristics. The second category bears closer examination as the "need for the sentence imposed" ought

a. To reflect the seriousness of the offense, to promote respect for the Law, and to provide punishment for the offense
b. To afford adequate deterrence to criminal conduct
c. To protect the public from further crimes of the defendant
d. To provide the defendant with needed educational or vocational training, medical care, or other correctional treatment in the most effective manner

Of these, public protection is relevant to the forensic evaluation, as factors that increase the risk of relapse or recidivism such as medication noncompliance can usefully be included without making a prediction or suggesting a disposition. Especially important would be specific recommendations for mental health services and treatment for the defendant's mental disorder and related medical conditions.

A survey of contemporary state sentencing statutes by Johnston (2014) revealed a variety of factors for judges to consider in sentencing, including the offender's treatment needs such as hospital care, the defendant's capacity to cope in a correctional setting, vulnerability to harmful effects of imprisonment as a mitigating factor, and a defendant's need for specialized treatment. It behooves the evaluating psychiatrist to become familiar with the state's sentencing statute.

EVALUATION AND REPORT

The presentencing psychiatric evaluation and report is organized much like forensic evaluations and reports described in the respective chapters of this text. The approach is especially similar to that for criminal responsibility. Records to be reviewed include medical, school, mental health, substance abuse, and criminal records. Collateral interviews with friends and family must address "all known aspects of the defendant's life … regardless the level of personal sensitivity" (Atkins and Watson 2011, 56). Inquiries should be made about family history of mental illness, substance abuse, and childhood sexual, physical, and emotional abuse; as well as nonabusive trauma. In order to identify mitigating factors, the defendant's family and friends should be told of the importance of full disclosure (p. 56).

In felony cases a presentence investigation is prepared by a probation or parole officer. The resulting "sentencing assessment report" should include information about the defendant's personal and family history, his or her prior criminal record, and often proposed conditions for probation (Dierker 2013). The psychiatrist who conducts a presentencing evaluation should request any sentencing assessment report prepared by a probation/parole officer or other mental health professional with reference to the present or any prior cases of the defendant.

Psychological testing should be considered as a component of the psychiatric presentencing evaluation, particularly when cognitive impairments are suspected. In addition to the often used psychological tests, such as the Wechsler Adult Intelligence Scale, 4th edition (WAIS-IV) and the Minnesota Multiphasic Personality Inventory-2 (MMPI-2), instruments of special relevance to sentencing include measures of relevant risks and needs for planning supervision, such as the *Level of Service/Case Management*

Inventory (LS/CMI), and of risk for recidivism and violent recidivism. Several instruments have been designed to address recidivism for sexual offenders, such as the *Rapid Risk Assessment for Sex Offenders Recidivism* (RRASOR) and the *Sex Offender Risk Appraisal Guide* (SORAG) (Atkins and Watson 2011, 60–62), the *Hare Psychopathy Check List-Revised Second Edition* (PCL-R), and the *Historical/Clinical/Risk Management-20* (HCR-20: Version 2).

To be explored and incorporated as appropriate, Atkins and Watson (2011, 64–66) identify the following domains as especially relevant to sentencing: cultural background, military experience, gang involvement, socioeconomic status, circumstances of the index offense and defendant's state of mind at the time, the defendant's character, and victim-related variables.

The report should additionally include relevant jurisdictional law on sentencing that is being addressed, for example, Section 5K2.13 of the Federal Sentencing Guidelines, if the report is prepared for federal sentencing (Atkins and Watson 2011, 66–68). A useful presentencing report addresses those factors discussed here as particularly relevant to sentencing.

SUMMARY

Psychiatric presentencing evaluations can be requested to address competence to be sentenced, treatment consideration, mitigation, or a combination of these purposes where the offender has a mental disease or defect. Competence to be sentenced can be a type of adjudicative or procedural competence or, alternatively, competence to serve a particular sentence such as imprisonment. Psychiatric assessments can serve one or more of the four traditional legal purposes of punishment, even retribution. Accordingly, the psychiatrist should endeavor to understand how the evaluation can be used to assess punishment and to address the defendant's mental health needs, respectively.

SUMMARY KEY POINTS

- Psychiatric presentencing evaluations should not be recommended penal dispositions.
- Even without recommending specific criminal sentencing, the psychiatrist should anticipate that presentencing evaluations will be used to determine the nature and severity of punishment.
- Allowance for mental illness under the penological theory of retributivism can serve the legal principles of avoiding violation of human dignity and supporting the principle of equal impact.
- A need for the sentence imposed of special relevance to psychiatric presentencing reports is "to provide the defendant with needed educational or vocational training, medical care, or other correctional treatment in the most effective manner."
- Among the sources of information, the examining psychiatrist should request the sentencing report prepared by a probation/parole officer, as well as other forensic reports concerning the defendant.

ACKNOWLEDGMENT

Many thanks to E. Lea Johnston, Associate Professor of Law, University of Florida, Levin College of Law, for her useful suggestions in the finalization of this chapter.

Specific issues in psychiatric malpractice

ROBERT WETTSTEIN

INTRODUCTION

In this chapter, several of the specific liability issues that concern mental health professionals—especially psychiatrists—will be discussed and reviewed. As space does not permit inclusion of all of the possible areas of psychiatric negligence that are not covered elsewhere in this volume, the present review is highly selective. The chapter will focus on negligence liability rather than liability for breach of contract, civil rights, intentional torts, or fraud, which can also be brought against the psychiatrist, whether based on the same conduct or otherwise. The present topics include error in medicine, law of negligence, tort reform, psychopharmacology, seclusion and restraints, suicide and attempted suicide, supervision of other health-care professionals, and consideration of the issues related to the use of electronic medical records.

ERROR IN MEDICINE

Error in medicine has attracted increasing attention from a variety of parties: physicians and their professional organizations, injured patients, plaintiff and defense attorneys, liability insurance companies, government agencies, researchers, public policy experts, and public health experts. Terminology in this field is complex and controversial, with the use of different definitions of error in medicine. Terms such as error, accident, inadvertent injury, complication, medical injury, therapeutic misadventure, iatrogenic injury, adverse drug event, and negligent adverse event are used in different accounts or studies of this issue. Errors in medicine are not necessarily equivalent to negligence and may or may not be necessarily preventable or harmful to the patient.

The true incidence and typology of medical errors in general medical populations are unknown, because studies have only been conducted in selected patient groups such as surgical or intensive care hospitalized patients or other subspecialized care populations. There is no national database of medical error, though some states compile and report more severe errors such as wrong-side surgery, and patient deaths. Research methods in this area include retrospective record review (Thomas et al. 2000; Hayward and Hofer 2001), computerized detection using electronic health records, physician self-reporting of incidents (O'Neil et al. 1993), patient self-reporting of incidents, or prospective observational studies (Andrews et al. 1997), some using standardized patients (Graber 2013). Of all medical errors, diagnostic errors are the most common, most costly, and most dangerous (Therani et al. 2013). Empirical research indicates that medical negligence is not rare, occurring in as many as 4% of hospital admissions, resulting in 44,000–98,000 deaths every year in American hospitals (Kohn et al. 2000), in addition to costly subsequent consequential medical care (Andrews et al. 1997). Operative complications and adverse drug effects are among the most common types of adverse events (Thomas et al. 2000).

Despite the considerable incidence of medical error, few injured patients actually file a legal complaint (Localio et al. 1991). Fewer than half of patient–plaintiffs receive any payment, and only about 10% of medical malpractice cases proceed to trial (Taragin et al. 1992). At trial, about one-fourth of medical malpractice plaintiffs prevail compared with one-half of plaintiffs in other tort cases (Litras et al. 2000). Thus, even though many malpractice cases are brought by patients who were treated negligently, these patients were infrequently compensated (Localio et al. 1991).

There is geographical variation in the incidence of medical malpractice litigation, its outcome, and liability insurance premiums, even from county to county within the same state. There is considerable variation in the annual prevalence of medical malpractice litigation across physician specialty; in one study, this ranged from 2.6% in psychiatry to 19.1% in neurosurgery (Jena et al. 2011). In psychiatry, the incidence of malpractice litigation against psychiatrists has ranged from 4% to 8% annually, since the 1980s. One national study found a decline in the frequency of medical liability paid claims, and a flat or declining level of compensation payments and insurance costs between 2004 and 2013 in five representative geographical areas,

though the proportion of cases that resulted in compensation to the patient–plaintiff has been unchanged (Mello et al. 2014).

A public health and safety approach to medical error has been recommended, given contemporary advances in knowledge of human factors and injury prevention (Leape 1994; Kohn et al. 2000). This approach includes mandatory reporting of serious patient injuries or deaths due to medical error, which is not uniformly required in the United States. Effort is focused on the systematic identification and prevention of error through the proper design of the medical workplace, recognizing that injuries often result from failure of a complex, interdependent system rather than a single individual acting in isolation. Accompanying that cultural shift is an approach to error that is not blaming of the involved health-care professional but rather accepting and future oriented with regard to error prevention.

Handling medical error

A physician or associated health-care professional is faced with a dilemma when he or she becomes aware of an error in the patient's care, especially when the error is harmful to the patient and the patient and family are unaware. In one survey of internal medicine residents, only 54% discussed the mistake with their attending physicians, and only 24% informed the patient or families (Wu et al. 1991). Disclosing a serious error to a patient or family member is typically discouraged by risk management staff and legal counsel at hospitals and clinics, for fear of increasing the likelihood of a lawsuit for the error (Studdert et al. 2007). The presence of the National Practitioner Data Bank, though limited in its actual impact, also serves as a deterrent to spontaneous reporting of serious error (Baldwin et al. 1999).

The ethical theories of consequentialism and deontology each argue for a physician's duty to disclose significant medical error to patients and families, and professional medical associations have adopted policies favoring disclosure for ethical reasons (Wu et al. 1997). The Veterans Administration has adopted a system-wide policy of disclosing medical error to patients and family when that error has resulted in loss of a patient's function, earning capacity, or life, while providing assistance to them in filing a claim against the facility (Kraman and Hamm 1999). Empirical data pursuant to this practice at one facility demonstrated that claim frequency and severity data were moderate to those at comparable facilities (Kraman and Hamm 1999). Surveyed internal medicine patients at an outpatient facility indicated that they desired an acknowledgment from their physicians of even minor errors (Witman et al. 1996). Such honesty likely undercuts anger and vengefulness of patients and their families, the latter of which can prompt litigation demanding excess or even punitive damages (Hickson et al. 1992; Witman et al. 1996). Beyond being the "best defense," acknowledgements of medical error and apology also promote open communication between physicians and patients (Witman et al. 1996; Shuman 2000) and provide patients with information that they may need to make decisions regarding their subsequent health care. Such an approach contrasts with the earlier approach of "deny and defend" any professional misconduct. Yet, such a practice of disclosing one's own medical error does not necessarily extend to the situation of a psychiatrist who learns of a medical error made by another physician in the care of their joint patient.

To promote error disclosure and transparency, the majority of states in the United States have enacted "apology" statutes that immunize health-care professionals from disclosing the error to patients and families (McDonnell and Guenther 2008). In such jurisdictions apologies involving the expression of sympathy, regret, and condolence may not be admitted as evidence of negligence in subsequent litigation against the treatment provider. Statements of fault, however, are often not protected by these statutes (Mello et al. 2014). It is unclear whether such an approach by health-care professionals actually reduces litigation volume or cost (Studdert et al. 2007; Saitta and Hodge 2012; Mello et al. 2014).

LAW OF NEGLIGENCE

Medical malpractice litigation has been an important issue in the United States only in the last 150 years (Mohr 2000). Malpractice litigation has been driven by medical factors such as the promulgation of uniform accepted clinical standards of care in a social climate of professionalism. Legal factors such as the availability of professional liability insurance, presence of contingent plaintiff attorney fees, legal right to jury trial with use of citizen juries, and pleading of malpractice as a tort rather than a contract also contributed to sustaining malpractice litigation (Mohr 2000). The goals of medical malpractice litigation include compensating patients injured through negligence, deterring unsafe medical practice, and obtaining corrective justice (Studdert et al. 2004).

Tort law, the law of civil injury, is defined by state or federal statute and case law. By law, a physician has a duty to the patient to use that degree of skill and care that is expected of a reasonably competent physician in the same class to which he or she belongs, acting in the same or similar circumstances. A patient–plaintiff has the burden to prove that the physician had a duty to provide appropriate evaluation and treatment and that the physician failed to do so. Medical malpractice litigation is therefore fault based, and deviations in the standard of appropriate care occur by errors of omission or commission. The plaintiff must further prove that the defendant physician's failure to provide appropriate care and treatment to the patient was proximate cause of the physical or emotional harm to the patient. Harm to the patient that occurs through causes other than the defendant's negligence (e.g., the natural course of the underlying disease) is not the responsibility of the defendant. Liability can also be avoided if the defendant made an error in judgment in the assessment and care of the patient–plaintiff, despite the adverse outcome of the case.

Standards of medical care are predominantly national in origin, but some jurisdictions apply a local or regional standard of care. The standard of care is not that of the most highly skilled or even the average physician; it may be met if it is the standard used by a significant minority. In the litigation, the plaintiff and defendant attempt to establish the standard of care, and its breach, through the use of authoritative professional literature, practice guidelines, applicable government regulation, hospital and clinic policy, accreditation standards, and expert witness testimony (Ayers 1994; Hyams et al. 1995; Shuman 1997). However, even practice guidelines can widely differ in a particular medical specialty area, leading to uncertainty regarding the standard of care (Morreim 1997). Evidence-based medicine has been introduced as a principle to apply empirical knowledge to the practice of medicine and help identify what is appropriate care (Guyatt et al. 2000). However, alternate schools of thought, through a reputable minority of practitioners, can also set the acceptable standard of care in a given situation. Relevant evidence must pertain to the standard of care at the time of the alleged negligence and not at a subsequent time when medical advances may have occurred.

TORT REFORM

Tort reform has addressed the problems presented by the current legal approach to medical malpractice in the United States. These problems have included difficulty identifying negligent medical care, failure to compensate patients subjected to medical error, litigation-induced emotional and financial burden to the defendants (Bourne et al. 2015), failure to deter physician negligence, the cost of practicing defensive medicine by physicians when they order unnecessary and expensive tests and procedures, inefficiency in the system with long processing and litigation delays, and administrative or legal costs that occupy much of the insurance premium dollar. Federally sponsored tort reforms have not been enacted due to political reasons, although individual states have had variable success in this area.

More than half of the states have limited noneconomic damage awards to plaintiffs, and these have been repeatedly challenged in court as unconstitutional or otherwise illegal. State appellate courts have, however, upheld such statutory limits (e.g., *Chan v. Curran* 2015). These limits on pain and suffering and limits on plaintiff attorney fees have contributed to stabilization in the numbers of medical malpractice claims, pay outs, and insurance premiums. They have been a model for tort reform in other states (Mello et al. 2014).

Additional tort reforms include tightening of medical expert witness qualifications to those in the regular practice of medicine in the particular area in question, changing the medical standard of care from that of professional negligence to gross negligence, and pretrial screening with a certificate of merit requirement before the initiation of litigation. The most ambitious tort reform, adopting an administrative rather than judicial compensation system for medical injuries, has not occurred in the United States but has occurred in Sweden and New Zealand (Mello et al. 2014).

Reforms outside of the legal system, including open disclosure of medical errors, communication transparency, and early offers to settle claims out of court have been adopted by large health-care systems (Kachalia et al. 2010). Evaluating the impact of specific tort reforms in medicine has yielded inconclusive results, given methodological limitations of longitudinal research conducted without controlled studies (Kachalia et al. 2010; Mello et al. 2014; Waxman et al. 2014).

PSYCHOPHARMACOLOGY

Errors in prescribing and dispensing medications constitute a large proportion of medical errors and iatrogenic patient injuries in the United States (Bates et al. 1995; Classen et al. 1997). In nonpsychiatric hospitals, errors in prescribing and adverse medication events are relatively common and often preventable (Leape et al. 1995; Lesar et al. 1997). Such errors occur due to inadequate information about the patient, lack of knowledge of or experience with the medication, inadequate patient monitoring and name confusion, faulty interaction with other medical services, incorrect dosage calculation, drug–drug interaction, and packaging mix-ups, among others. Attempts to improve the systems by which medications are ordered, dispensed, and administered, such as bar coding in hospitals, have been frequently adopted to reduce adverse drug events (Bates et al. 1999). Computerized prescribing of medication, based on databases including the patient's drug and illness history, formulary guideline reference, and scientific drug information, enhances prescription efficiency and accuracy (Schiff and Rucker 1998).

Prescribing psychotropic medication increases the psychiatrist's exposure to professional liability claims (Brackins 1985; Wettstein 1985; Dukes and Swartz 1988; Slovenko 2000). It accounts for some of the excess professional liability claims that psychiatrists face relative to other mental health professionals. In addition to risking professional liability, psychiatrists—like all physicians—may be sanctioned by state and federal prosecutors in criminal actions, or state and federal licensing agencies (e.g., state medical board, U.S. Drug Enforcement Agency). These actions usually pertain to physicians who inappropriately administer, prescribe, dispense, or fail to keep proper records for controlled medications. Failure to obtain relevant history and conduct appropriate physical examinations before prescribing controlled medication can be considered negligent care and is often illegal.

Pharmaceutical manufacturers are often sued because of the manufacture, distribution, and marketing of psychotropic medications. The law of product liability requires that a manufacturer directly warn the ultimate consumers of the known risks of the use of the product. For most classes of prescription medication, however, the pharmaceutical manufacturers are governed by the "learned intermediary rule" that states that the manufacturer has a duty to inform

the prescribing physician, but not the patient, of important drug information (Brackins 1985). The learned intermediary doctrine relieves manufacturers of tort liability when adequate warning has been provided to the prescribing physician. Professional (negligence) liability principles apply to prescribing physicians, but there is some uncertainty whether negligence or strict liability principles apply to pharmaceutical manufacturers (Brackins 1985; Ausness 1989–1990). Nevertheless, plaintiffs searching for the "deep pocket" often sue the manufacturer as well as the prescribing physician, health-care facility, and pharmacist.

Psychiatrists risk negligence liability in the following areas when they prescribe psychotropic medication (Wettstein 1983, 1988):

- Failure to take an adequate history prior to prescription
- Failure to obtain an adequate physical examination
- Failure to obtain an adequate laboratory examination
- Lack of indication for a prescription and off-label use
- Contraindication for a prescription
- Improper dosage
- Improper duration
- Failure to recognize, monitor, and treat side effects
- Failure to abate drug-drug or food-drug reactions and interactions
- Failure to consult with other physicians
- Failure to properly diagnose and treat the patient's disorder
- Failure to obtain informed consent to treatment
- Improper record-keeping

Typically, the plaintiff will allege several areas of negligence in the litigation against each defendant rather than a single cause of action. Litigation has been brought against physicians for prescribing all classes of psychotropic medications, so the following is a selective sample. Dispensing of medication in the office creates different obligations but will not be considered here due to its infrequency among psychiatrists.

Failure to take an adequate history

In *Leal v. Simon* (1989), an institutionalized intellectually disabled man was stabilized on haloperidol for self-abusive behavior. He was transferred to a community facility and began treatment with the defendant psychiatrist. The patient was stable for over a year, and the psychiatrist reduced his medication dose. The psychiatrist indicated that the medication withdrawal was necessitated by a state audit regarding medication use in the intellectually disabled, as well as the risk of tardive dyskinesia (TD). Within a month of the medication discontinuation, the patient deteriorated, requiring hospitalization and larger doses of haloperidol. He was returned to the state institution, developed contractures of his extremities, and became wheelchair-confined. The jury found that the psychiatrist was negligent in failing to review the patient's history, failing to obtain the patient's complete medical records from the transferring agency, and reducing the medication so abruptly.

Empirical data have been accumulating regarding the association between the use of psychotropic medication, particularly benzodiazepines and sedative-hypnotics, and automobile or other accidents such as falls (Barnas et al. 1992; Barbone et al. 1998; Thapa et al. 1998; Rapoport et al. 2011; Orriols et al. 2012; Kolla et al. 2013). In *Watkins v. United States* (1979), the prescribing physician was found negligent for prescribing diazepam to a patient without taking an adequate psychiatric history or reviewing the patient's psychiatric records, which led to a motor vehicle accident.

Lack of indication for a prescription

A psychiatrist prescribed diazepam for a man who, while driving his car the next day, collided head-on with a motorcycle. It was alleged that the patient was under the influence of beer and diazepam, which he had obtained for nonmedical purposes. The seriously injured plaintiff alleged that it was negligent to prescribe diazepam to a person who was likely to abuse drugs. A $410,000 out-of-court settlement was reached with the psychiatrist and other parties (*Munsell v. Lynk* 1983).

Contraindication for a prescription

Upon admission to a hospital, a male patient informed the staff that he was allergic to antihistamines because they caused urinary retention. He was nevertheless prescribed hydroxyzine and trifluoperazine. When urinary retention developed, the hydroxyzine was reduced and later discontinued, but complications developed, including a prostatic infection, the need for a catheter, and eventual prostatic resection. Expert testimony indicated that the hydroxyzine prescription was negligent given the patient's history, and that the hydroxyzine caused the bladder damage. A judgment for the plaintiff of $20,000 was awarded (*Miller v. U.S.* 1976).

More generally, off-label use of U.S. Food and Drug Administration (FDA)-approved psychotropic medications is common and a well-accepted form of medical practice, though with liability risk (Weiss et al. 2000). Off-label use consists of prescribing a medication for a medical condition not already FDA approved, or prescribing for a different patient population or in a different dosage than approved. Off-label use is not *per se* a deviation from the standard of accepted psychiatric care. In some cases, failure to prescribe a medication for an off-label use could be considered a deviation from the standard of care. Several professional medical associations have adopted specific policies on the use of off-label medications, typically noting that such use is appropriate when based on sound scientific evidence and medical opinion (Henry 1999). Case law generally has recognized the appropriateness of off-label prescribing (Kuntz 1998).

Failure to recognize, monitor, and treat side effects

In *Clites v. Iowa* (1980), the parents of a mentally retarded male at a state facility sued the state for negligence and failure to obtain informed consent. Several physicians had treated the patient with antipsychotic medication since age 18 for "aggressive behavior." After 5 years, tardive dyskinesia (TD) of the face and extremities was diagnosed. The trial court ruled that medication had been inappropriately prescribed, and that the patient was improperly monitored over the years. The trial court also ruled that the patient's parents, his legal guardians, "were never informed of the potential side effects of the use, and prolonged use, of major tranquilizers, nor was consent to their use obtained," thus violating the "standard that requires some form of informed consent prior to the administration of major tranquilizers." The parents had not been informed of the risks attendant to the treatment program, and the trial court rejected the defendant's argument that the parents had implicitly consented. The trial court awarded $385,165 for future medical expenses and $375,000 for past and future pain and suffering. This was subsequently upheld in the Iowa Court of Appeals (*Clites v. Iowa* 1982).

Prescription of an improper dose and duration

In *Hedin v. U.S.* (1985), the plaintiff was hospitalized for treatment of alcohol abuse and treated with thioridazine and then chlorpromazine as an outpatient. He continued to take chlorpromazine nearly 4 years before his physicians detected his TD and withdrew the medication. Though the patient had been aware of the movements involving the face, mouth, trunk, and extremities, he was unaware they were due to the medication. The defendant acknowledged having prescribed excessive amounts of medication over a prolonged period of time without proper supervision. Damages of nearly $2.2 million were awarded because the plaintiff had become functionally disabled from the dyskinesia.

Failure to diagnose and treat with medication

New psychotropic medications are continually being developed and released for disorders that were previously untreatable with medication, and new uses are being found for existing medications or combinations of medications. Cost-containment strategies in mental health care emphasize the need to provide effective treatment at the lowest expense, and somatic treatments can often fill this role. Slawson (1991) reported that patient complaints about the ineffectiveness or inappropriateness of medication far exceeded those about medication side effects. In cases of delayed or no improvement, liability can include the failure to obtain consultation from a clinician experienced with psychotropic medication and electroconvulsive therapy.

A related liability concern is the alleged failure to use psychotropic medication. A much-publicized case involving failure to treat depression with antidepressant medication was settled for an undisclosed amount after an arbitration panel awarded the plaintiff $250,000, without establishing a legal precedent (*Osheroff v. Chestnut Lodge* 1985). A similar action was brought by a patient who was treated for dysthymic disorder with psychoanalysis for 8 years after he had refused treatment with medication (*Cobo v. Raba* 1998). At trial, the jury found for the plaintiff, who was a physician specializing in infectious disease. On appeal, however, the North Carolina Supreme Court reversed and remanded, ruling that the defendant psychiatrist was entitled to a jury instruction on contributory negligence by the plaintiff, a legal doctrine in the state that permits a defendant to prove that the plaintiff's injuries were proximately caused by his or her own negligence.

Standard of care in psychopharmacology litigation

As in all medical negligence litigation, the plaintiff alleging negligence in prescribing must establish the relevant standard of care and prove that the defendant deviated from that standard. For several reasons, standards of care in psychopharmacology are often more elusive than they may seem. New psychotropic medications of all types are continually being introduced into the marketplace; for example, second-generation antipsychotic medications, with their lower incidence of movement disorders than conventional antipsychotic medications, have become a standard of care in the treatment of schizophrenia (Chiles et al. 1999; Slovenko 2000; Rabinowitz et al. 2001). However, second-generation antipsychotic medications carry their own potential sources of liability, including failure to recognize or manage the metabolic side effects that are frequently seen with their use (Mossman and Steinberg 2009).

Finally, decisions to treat patients with pharmacotherapy, especially in high-risk clinical situations such as pregnancy, are typically complex, risk–benefit processes dependent on factors related to the physician, patient, and family members (Wisner et al. 2000). In adverse drug reaction liability cases, the plaintiff may introduce the manufacturer's labelling (e.g., medication package inserts and the *Physicians' Desk Reference*) as evidence of the defendant's departure from the standard of care. In some jurisdictions, such evidence is considered *prima facie* evidence of negligence, though expert medical testimony will still be necessary to establish that the patient's injury resulted from the negligence (*Mulder v. Parke Davis & Co.* 1970; *Haught v. Maceluch* 1982). Other jurisdictions, however, have rejected the manufacturer's labelling as conclusive of negligence, and require expert testimony as well as the relevant medical literature to establish the standard of care (*Haven v. Randolph* 1972). Thus, compliance with the manufacturer's

published recommendations will not invariably negate liability, and deviation will not necessarily impose liability (Yacura 1984).

SECLUSION AND RESTRAINTS

The use of seclusion and restraints in mental health or nursing home settings is highly regulated by state and federal regulations, state statutes, state and federal constitutional provisions, and standards set by The Joint Commission. Federal regulations were adopted by the Health Care Financing Administration in 1999 for Medicare-funded hospitals (HCFA 1999), and a federal statute was enacted in 2000 applicable to public or private general hospitals, nursing facilities, and residential treatment centers for children and youth (Public Law 106-310). The laws contain detailed rules about the definitions of seclusion and restraint, indications (e.g., patient age, diagnosis, symptoms), exceptions (e.g., time outs in a nonlocked setting to calm a patient), contraindications, role of physician and nursing staff, monitoring practices, need for consultation or review, need for patient consent, documentation of pertinent findings and decision making, and reporting of injuries or deaths resulting from their use. While burdensome to physicians and facilities alike, such rules are promulgated to protect patients from the emotional and physical harms that can occur from their use (Fisher 1994; Appelbaum 1999).

Although the use of seclusion and restraint is not a frequent source of litigation for psychiatrists and hospitals, liability can occur (Johnson 1990; Coffin 1999). In *Youngberg v. Romeo* (1982), a committed, mentally retarded person's constitutional right to be free from undue bodily restraint was recognized. Psychiatrists incur negligence liability for seclusion and restraints when overuse results in patient injury or death. The physicians in *Hopper v. Callahan* (1990), in which a female patient died in seclusion, were alleged to have failed to exercise professional judgment in ordering the seclusion and in failing to provide appropriate medical care.

Negligence liability can also occur for the failure to use appropriate restraints resulting in injury to staff, other patients, or the patient himself or herself. A hospitalized patient in an acute psychotic episode managed to escape from full leather restraints while unmonitored, and fled the hospital (*Rohde v. Lawrence General Hospital* 1993). He drove off in an unlocked automobile taken from the hospital parking lot and crashed into a fence, suffering serious injuries. Suit was brought against the hospital, nursing staff, and physician.

SUICIDE AND ATTEMPTED SUICIDE

Suicide and attempted suicide are among the most common and most expensive professional liability claims against mental health professionals and facilities (Bongar 2002). Damages for the survivor of a suicide attempt can exceed those for a completed suicide, due to the need for continuing medical and rehabilitative expenses for serious, disabling, but nonlethal injuries (e.g., paraplegia, burns, neuropsychological deficits). Income losses for middle- or upper-income individuals who commit suicide can reach into the millions of dollars.

Liability may occur for suicides during hospitalization, shortly after release from the hospital, and on an outpatient basis. Each situation presents different clinical and legal issues (Klein and Glover 1983). Liability is more likely with hospital suicides (Bongar et al. 1993), given the staff's greater control over the inpatient setting. Although the risk factors for hospital suicide are not empirically known, they may differ from those of outpatient suicide (Proulx et al. 1997; Powell et al. 2000).

Generally, liability is predicated on an inadequate assessment of suicide risk, and/or an inadequate response to that risk, which is proximately related to the suicide (Simon and Hales 2012). An assessment of suicide risk is ideally a comprehensive investigation of cognition, emotion, and behavior with regard to present and past self-destructiveness (Joiner et al. 1999). The clinician examines suicide ideation, suicide intention, suicide plan, availability of weapons, attitudes about suicide, past history of suicide attempts, and behavioral impulsivity. Additionally, clinical dimensions such as depression, hopelessness, and psychosis are assessed. The patient's ability to monitor his or her own suicidality and report it to the clinician should also be assessed (Gutheil et al. 1986). Repeated suicide assessments are typically necessary, especially when treating depressed or severely character-disordered hospital patients and those who are chronically suicidal, because suicide impulses can fluctuate in their presence and severity.

Once the suicide assessment has been completed, the clinician must respond in proportion to the level of risk identified. Both treatment and security/observation measures must be taken to reduce risk. This requires balancing treatment versus security needs, which may be mutually contradictory (e.g., prescribing higher medication doses with more lethality and potential for response versus lower doses; increasing hospital suicide precautions versus permitting more freedom to pursue treatment opportunities). Courts can be sympathetic to these conflicts; in *Topel v. Long Island Jewish Medical Center* (1981) an appellate court ruled that professional judgment determined whether a suicidal patient should be monitored continuously or at 15-minute intervals, and that it was proper for the defendant physician to evaluate the expected benefits and risks of constant surveillance. Suicides that occur upon release from the hospital raise questions about negligent release, either inadequate risk evaluation prior to release, or improper aftercare treatment plans.

No-suicide "contracts" and decisions to discharge a patient "against medical advice" are often used by clinicians under the erroneous belief that such practices will protect them from liability. Neither defensive measure reduces the likelihood of litigation, adverse legal outcome, or suicide (Devitt et al. 2000; Kroll 2000). Rather, contracting for safety can create a barrier to communicating intense

emotional distress and can interfere with the therapeutic alliance. Staff may inappropriately reduce their attention to the patient's suicide potential, thereby deluding themselves that the patient is safe and creating a false sense of security (Miller et al. 1998). "No-suicide" contracts should not substitute for ongoing comprehensive risk assessment and treatment planning (Simon 1999).

NEGLIGENT SUPERVISION AND COLLABORATION

The psychiatrist incurs liability risks when he or she supervises or collaborates with other mental health professionals in the care of a patient. The nature and extent of the risk depend on the roles and responsibilities of the respective clinicians, the type and severity of the patient's mental disorder, the forms of psychiatric treatment that are provided to the patient, and the administrative system of clinical care in which the patient is seen. For present purposes, we can distinguish among supervision, consultation, and collaborative treatment—sometimes called "medical back-up," "dual treatment," "shared treatment," or "split treatment" (Sederer et al. 1998). In a supervisory relationship, the supervisee is expected to comply with the recommendations of the supervisor. In contrast, consultation involves two or more independently licensed or fully credentialed professionals. In a collaborative relationship, two or more licensed or credentialed professionals share the patient's care, with each of them independently responsible for particular aspects of that care.

Psychiatrists who supervise other clinicians bear considerable clinical and legal responsibility for that clinician's work. According to the legal doctrine of *respondeat superior*, the supervisor incurs vicarious liability for the supervisee. Thus, the physician in *Andrews v. United States* (1984) was found to have negligently supervised his assistant's counselling that eventuated in sexual intercourse. The presence of a supervisory relationship can be suggested by a system of care in which the psychiatrist signs or reviews team treatment plans, or billing claim forms for a patient, even though the psychiatrist has no formal supervisory role in the team. Similarly, the concept of the physician as "captain of the ship" is still prevalent, despite actual clinical practice to the contrary. And courts have held trainees to the same standard of care as fully trained professionals, so the supervisor does not entirely shoulder the liability.

In contrast, consultants should bear less clinical and legal responsibility for patient care than supervisors, especially if the consultant has not personally examined the patient and billed for the consultation. In that case, a court may rule that there is no physician–patient relationship, which is a predicate for professional liability (*Hill by Burston v. Kokosky* 1990). Depending on the clinical context, consultants may have clinical and legal responsibilities to perform adequate assessments of the patient, to coordinate care with the attending physician or psychotherapist, and to document their findings and decision making. To the extent that consultants participate in activities relating to treatment of the patient, they share the same liability exposure as treating psychiatrists. Malpractice claims against consulting psychiatrists have been litigated and settled out of court (Garrick and Weinstock 1994).

Psychiatrists who collaborate with nonmedical mental health practitioners in the care of a patient, whether at an agency or in private practice, might in theory have limited liability for patient care, given their restricted clinical activities such as infrequent and brief contact with a patient only for prescribing and monitoring psychotropic medication, and responding to emergency situations necessitating hospitalization (MacBeth 1999, 2001). In such a practice, the psychiatrist should not, in theory, have responsibility for the psychotherapist's errors and omissions. Yet, the legal system may not appreciate the critical distinctions between supervision, consultation, and collaboration, and consequently, split treatment arrangements may not minimize liability for collaborating psychiatrists. For instance, a plaintiff's attorney can attempt to distort a collaborative relationship into a supervisory one.

Liability exposure is also increased for the psychiatrist in clinical systems of care: (a) in which the psychiatrist is unable to see a patient in a timely manner to assess a patient's clinical change; (b) in which the psychiatrist is given medication responsibility for large numbers of patients; (c) when the psychotherapists are inadequately trained and supervised; (d) when mechanisms are inadequate to facilitate genuine collaboration and sharing of information between the psychiatrist and psychotherapist; and (e) when there are multiple therapists and multiple psychiatrists providing care to a single patient. Through the use of "joint and several liability," split treatment with multiple defendants can result in the well-insured psychiatrists having to provide most or all of the legal judgment against the defendants, especially when the nonphysician codefendants are uninsured or underinsured (Meyer 2012).

In collaborative treatment situations, the cotherapists need to clarify the nature of their relationship and their respective roles and responsibilities (Gutheil 1994; MacBeth 1999). A written contract or letter of agreement between the cotherapists can be useful for this purpose. It should be clear, for example, whether the psychiatrist is responsible in any way for the nonpsychiatrist's psychotherapy, or is only providing pharmacotherapy services. A judge or jury in a malpractice case could otherwise assume that the psychiatrist had supervisory authority over the psychotherapist. The psychotherapist's responsibility, if any, for monitoring medication response and side effects should also be clearly defined. There should be ample opportunities for interaction and coordination between the psychiatrist and psychotherapist, whether on a regular or crisis basis, to minimize miscommunication, splitting, and inconsistency in the treatment approach. Professional guidelines for such collaboration indicate that the patient should also be informed of each therapist's responsibilities and consent

to the free sharing of information between the physician and nonphysician (American Psychiatric Association 1980; Gutheil 1994).

ELECTRONIC MEDICAL RECORDS

Clinical documentation serves a multitude of functions, including recording a patient's clinical condition and response to treatment, communicating the provider's findings and activity to other providers, and risk management (Kuhn et al. 2015). Providers are typically cautioned to document a particular clinical or historical finding or course of action to provide proof that this occurred. Providers are incentivized to overdocument rather than underdocument a patient's care and treatment (Sheehy et al. 2014).

Electronic health-care records (EHR) have been widely adopted by health-care systems and individual practitioners due to the implementation of financial incentives and the ongoing change to a patient-safety culture in medicine. In theory, EHRs could enhance the quality of patient care through improved communication among providers for a particular patient, increased efficiency, standardization of documentation of treatment, prevention of duplicate testing and treatment, reduction of malpractice liability, and research opportunities to investigate treatment efficacy and utilization. However, health-care providers have reported a mixed response to their use due to the increased time demand to complete a detailed menu-driven computerized record, distraction from attending to the individual patient at the time of the visit, and the human and financial cost of EHR adoption.

EHRs create novel clinical, administrative, financial, and legal risks (Hoffman and Podgurski 2009). It is unknown whether EHR adoption reduces or increases medical malpractice risk to individual providers (Virapongse et al. 2008). These new risks include errors from providers using the system, as well as "bugs," design flaws, "crashes" of the EHR system, and loss of information security and patient privacy. The provider, as before, remains responsible for the accuracy of the health-care documentation (Mangalmurti et al. 2010). The "copy and paste" or cloning function of EHR has drawn particular liability concern, especially related to the potential misuse of EHR to up-code a particular patient service to fraudulently increase billing for services (Sheehy et al. 2014). Copy and paste misuse includes the failure to update previously recorded information from the EHR into the current visit due to carelessness, honest error, time pressure, or intentional misrepresentation. Providers can create standardized text and improperly export it to the records of other patients. Similarly, providers may fail to enter medication discontinuation orders or notes in the system so that the record contains inaccurate current information about a patient's medications. EHR systems often provide "decision support" information to providers to guide health-care decision making, which providers ignore at their peril. Finally, patient access to their EHR presents new and additional challenges to providers, especially in psychiatry where patient access to psychiatric records has traditionally been limited.

SUMMARY

Though psychiatrists are less likely sued than other physicians in other specialties, there are still many practice risks deserving concern, especially in a managed care, split treatment, clinical environment. Psychiatry is practiced in an increasingly regulated and complex legal and financial environment. Systems of care issues that reduce the risk of error in the practice of psychiatric medicine are at the incipient stage of development. This chapter has considered some of the generic psychiatric issues likely to be brought to litigation. Though specific clinical practices may change in future years, with the development of new problem areas, similar liability concerns will no doubt be applicable.

Psychiatric disability evaluations, workers' compensation, fitness-for-duty evaluations, and personal injury litigation

LIZA H. GOLD, JEFFREY L. METZNER, AND JAMES B. BUCK

INTRODUCTION

This chapter provides an overview of issues psychiatrists may face in disability determinations for the Social Security Administration (SSA), workers' compensation systems, private insurance policies, fitness-for-duty (FFD) examinations, and psychological damage claims in personal injury litigation.

PSYCHIATRIC ILLNESS, WORK IMPAIRMENT, AND DISABILITY

Functional impairment, with associated work disability, is one of the major consequences of mental illness (Gold and Shuman 2009; Schultz and Rogers 2010; Gold and Vanderpool 2011). Psychiatric disorders consistently rank in the top 10 leading causes of disability among adults in the United States and other parts of the world (World Health Organization 2008; Centers for Disease Control and Prevention 2011; National Institute of Mental Health 2014).

The SSA is the largest provider of disability insurance benefits in the United States, paying over $11.2 billion in disability benefits to approximately 10.2 million people in 2013 (SSA 2014a). Mental disorders rank among the highest percentages of long- and short-term claims among workers in private industry (Salkever et al. 2000; Dewa et al. 2002; Alpren and Bolduc 2010).

COMMON ISSUES IN DISABILITY EVALUATIONS

Disability evaluations and dual roles: "Wearing two hats"

Treating psychiatrists are drawn into providing disability documentation when a patient seeks disability compensation. SSA disability programs base decisions for eligibility for benefits primarily on information provided by treating clinicians. Workers' compensation systems typically rely on the treating clinician to provide ongoing reports regarding a patient's disability status. However, treating psychiatrists who become involved in their patients' disability claims face problematic implications of occupying these dual roles that can result in treatment dilemmas and disrupt the therapeutic relationship (Strasburger et al. 1997). Psychiatrists should consider referring to an independent psychiatrist under such circumstances (Gold and Davidson 2007; Gold and Shuman 2009; Vanderpool 2011).

The *Diagnostic and Statistical Manual of Mental Disorders, 5th edition* (*DSM-5*) and disability evaluations

The *DSM-5*'s (American Psychiatric Association 2013) changes in diagnostic and evaluation procedures are likely to have important consequences for disability evaluations (Gold 2014). The Global Assessment of Functioning (GAF) Scale has been removed, and a new rating methodology has not been endorsed. *DSM-5* has recommended that psychiatrists consider utilizing a new tool for assessment of global functioning and impairment, the World Health Organization Disability Assessment Schedule 2.0 (WHODAS 2.0) (Üstün et al. 2010). Unlike the GAF Scale, the WHODAS 2.0 is primarily a self-report instrument. However, government agencies and insurance systems are likely to continue requesting or requiring use of the GAF Scale in disability evaluations for some time (Gold 2014).

SOCIAL SECURITY DISABILITY INSURANCE

The SSA is responsible for administering the Social Security Disability Insurance (SSDI) Program (Title II) and the

Supplemental Security Income (SSI) Program (Title XVI). SSDI provides disability insurance coverage in the form of cash benefits for those disabled workers and their dependents who have contributed to the Social Security trust fund through the Federal Insurance Compensation Act (FICA) tax on their earnings. SSI provides a minimum income level for the needy, aged, blind, and disabled based on eligibility determined by statutorily defined need. Both SSDI and SSI programs require that individuals meet certain medical criteria to be eligible for benefits. The statutory definition of disability is the same in both programs; however, this discussion focuses only on impairment ratings for adults and the SSDI program.

Filing an SSDI claim and determining eligibility

SSDI was designed to provide replacement income for disabled workers. The SSA's process of determining disability emphasizes medical evidence that includes a signed report by the treating clinician concerning the applicant's medical history of impairment(s) that prevent work. If additional information is needed, the SSA may request a Consultative Examination (CE) from either the treating clinician or a nontreating mental health professional.

Each state's Disability Determination Service (DDS) makes the initial determination of eligibility for SSDI benefits. The DDS first assesses whether a claimant meets the SSA's definition of disability by sequentially addressing five threshold questions (SSA 2014b), specifically, whether a claimant

- Is engaged in substantial gainful activity
- Has a severe impairment or combination of impairments
- Meets or equals a "listed" or officially recognized impairment
- Is prevented by impairment(s) and residual functional capacity from engaging in relevant past employment
- Has the ability to engage in other gainful activity considering the claimant's education, past relevant experience, and residual functional capacity

There is a complicated appeal process for unfavorable DDS decisions (SSA 2014c).

Providing SSDI claim information

Information provided by treating clinicians is the cornerstone in the determination of eligibility for SSDI benefits. The SSA website provides a guide called "Medical/Professional Relations: Disability Evaluation Under Social Security," referred to as the "Bluebook," that helps clinicians understand and effectively document their findings for SSA review (SSA 2014b).

SSA defines total disability as the inability "to engage in any substantial gainful activity by reason of any medically determinable physical or mental impairment which can be expected to result in death or which has lasted or can be expected to last for a continuous period of not less than 12 months" (SSA 2014b). "Substantial gainful activity" (SGA) is considered to be any productive work of a nature generally performed for remuneration or profit, involving the performance of significant physical or mental duties or a combination thereof. This definition includes part-time work regardless of pay or similarity to an individual's former work. If jobs that the claimant could perform are available in substantial quantity somewhere in the country, then the claimant is not eligible for disability benefits (SSA 2014b). If claimants are earning over the statutorily prescribed level of income, SSA considers them to be engaged in SGA, and therefore not disabled. SSA will deny such claims no matter how serious the claimant's medical condition.

The SSDI claim analysis

The SSDI claim analysis begins with the diagnosis, based on "Paragraph A" criteria for a "listed" diagnosis. These are statutorily recognized diagnoses that the SSA has determined may meet the severity requirement of its definition of disability. The SSA lists nine categories of mental disorders, based on *DSM* diagnoses and their criteria (American Psychiatric Association 2013) (Table 33.1).

For each "listed" mental health diagnosis, there is first a description of the specific disorder. Second, paragraph "A" lists a set of medical findings that specify the symptoms needed to qualify for that diagnosis or listing. Third, paragraph "B" lists related functional limitations (Table 33.2).

Finally, for diagnostic categories statutorily defined as "chronic" (e.g., Intellectual Disability) paragraph C provides additional functional criteria that must be met for a claim to succeed.

Table 33.1 SSA listed categories of mental disorders

Organic mental disorders
Schizophrenic, paranoid, and other psychotic disorders
Affective disorders
Intellectual disability
Anxiety-related disorders
Somatoform disorders
Personality disorders
Substance addiction disorders
Autistic disorder and other pervasive developmental disorders

Table 33.2 SSA paragraph "B" functional limitations

Restriction of activities of daily living
Difficulty in maintaining social functioning
Deficiencies of concentration, persistence, or pace
Episodes of decompensation, each of extended duration

If the DDS deems that paragraph A criteria are satisfied, the SSA then assesses functional restrictions as delineated in paragraph B and, if necessary, paragraph C. The functional limitations and restrictions listed in paragraphs B and C must be the result of the clinical findings related to the mental disorder outlined in paragraph A.

Comprehensive definitions of Paragraph B functional limitations are provided by the SSA's "Bluebook." The SSA considers "C" criteria only if the "B" criteria in the relevant diagnostic groups are not met by the evidence. The paragraph C criteria recognize the significant impact of impairments related to certain chronic mental illnesses even when decreased by the use of medication or psychosocial factors such as placement in a structured environment.

The SSA recognizes that "listed" mental disorders do not encompass all types of clinical findings that may result in impairments severe enough to prevent work. Claimants may be found to be disabled based on reports indicating that they are experiencing medically equivalent impairments comparable to the impairments associated with the listed mental disorders (SSA 2014b). SSA also allows for consideration of the effects of a combination of impairments in determining disability for work.

Clinicians may also be asked to evaluate the elements of a claimant's "residual functional capacity" (RFC), defined by the SSA as "a multidimensional description of work-related abilities which an individual retains in spite of medical impairments" (SSA 2014b) (Table 33.3).

RFC is a description of what the claimant can still do in a work setting despite the limitations caused by impairments. If RFC is not sufficient to enable performance of work done previously, other factors will be considered in the assessment of ability to perform any other work, considering the claimant's age, education, work experience, and job availability in the national economy.

Information required for the psychiatric SSDI claim

The SSA's definitions and criteria for psychiatric disability translate into three key mental health concepts that must be present for an award of benefits:

1. Whether the claimant has a medically determinable impairment, referred to as a "listed" mental disorder
2. Whether the mental disorder has resulted in an inability to work
3. Whether the inability to work resulting from the mental disorder has lasted or will last for at least 12 months

Table 33.3 SSA definition of residual functional capacity (RFC)

Understanding and memory
Sustained concentration and persistence
Social interaction
Adaptation

SSDI reports should indicate whether a "listed" mental disorder or its equivalent is present. The SSA requires that clinicians provide information regarding

- The claimant's daily activities
- The location, duration, frequency, and intensity of symptom(s)
- Precipitating and aggravating factors
- The type, dosage, effectiveness, and side effects of any medication
- Treatments, other than medications, for the relief of symptoms
- Any measures the claimant uses or has used to relieve symptoms
- Factors concerning the claimant's functional limitations due to pain or other symptoms (SSA 2014b)

Clinicians should be certain to document whether the disorder interferes with the individual's ability to function in a work setting. They should comment on the degree and duration of functional limitation and indicate whether limitations have lasted or are expected to last at least 12 months, even if there may be some periods of time during the 12 months when the claimant may function well. These reports should contain a summary of the standard psychiatric examination, mental status examination, diagnosis, prognosis, treatment recommendations, and a description of limitations and remaining functional capacities regarding ability to perform ordinary activities. Lack of sufficient or relevant information in clinicians' reports can result in denial of a claim, a request for additional information from the treating clinician, or a request for a second opinion from a CE.

PRIVATE DISABILITY INSURANCE PROGRAMS

Various insurance companies offer individual or group disability policies designed to provide a disabled worker with greater financial benefits than those available through the workers' compensation system or SSA. Group policies are typically offered through employers as a benefit to employees; individual policies often attract self-employed professionals. Over time, the coverage offered by these policies has become more limited and more expensive (Anfang and Wall 2011).

Disability claims involve both forensic experts conducting independent medical examinations (IMEs) and treating clinicians. Treating clinicians are typically asked (with their patients' consent) to complete initial and ongoing claims forms certifying psychiatric impairment, provide copies of the treatment records, and perhaps speak with the claims adjustor or medical reviewer. If the insurance company has additional concerns or questions, they may request that the

claimant undergo an independent psychiatric disability evaluation.

The psychiatric disability Independent Medical Examination (IME)

An insurance company or its designee may contact a psychiatrist to arrange an IME. Typically, an IME will include a clinical interview and a review of records. The referral letter should list the opinions the insurer is seeking in the form of questions and all relevant definitions (e.g., disability). Depending on the terms of the policy, the insurer may inquire whether claimants are disabled for any occupation (i.e., any gainful occupation for which the insured is reasonably fit by education, training, or experience) or disabled for their own occupation (i.e., the material and substantial duties of the individual's current occupation) or both. The psychiatrist should also be provided with all relevant psychiatric, medical, and insurance records, including previous IMEs. An IME may also include review or collection of additional data from the treating mental health providers regarding diagnosis, treatment, symptoms, and work impairment. Psychological testing may also be requested.

Insurers typically request opinions regarding

- Diagnosis
- Specific symptoms and related work impairment
- Adequacy of treatment provided, whether additional treatment or different treatment modalities, such as occupational rehabilitation or pain management services, are indicated
- Prognosis and likely length of disability
- Restrictions (e.g., activities in which an individual should not engage due to the possible exacerbation of his or her condition)
- Limitations (e.g., activities the individual cannot perform due to impairments)
- Motivation for recovery
- The possibility of malingering or the effects of primary or secondary gain

Psychiatrists should obtain informed consent, preferably in writing, before beginning the IME. This includes explaining the purpose of the evaluation, the limits of confidentiality, the fact that no treatment will be provided, and to whom the report will be forwarded (Anfang and Wall 2011; Vanderpool 2011). If the evaluee is unwilling or unable to give informed consent, the psychiatrist should terminate the examination and inform the referral source.

In addition to the standard elements of medical and psychiatric history and treatment, evaluators should also review

- Current sources of income, disability benefits, and policy terms
- Current symptoms, stressors, and related impairments
- Whether the claimant is working in any capacity
- Descriptions of a current "good" day and "bad" day, and a "typical day" before and after the onset of disability
- Social, academic, and any other area of functioning prior to disability
- Factors that may be contributing to disability
- Efforts at and responses to treatment
- Efforts at returning to work during or after treatment
- Future plans and self-prognosis

The claimant's work history should include job description, functioning up to the time of disability, what contributed to the disability, and what has changed in terms of functioning. Psychiatrists should obtain a detailed past work history (e.g., types of positions held in the past, length of jobs, and reason for leaving—termination, filed a workers' compensation claim, etc.). A detailed criminal and civil legal history should also be obtained (Wall and Appelbaum 1998).

Secondary gain, potential malingering, and motivation to return to work are particularly relevant and complex in the private disability insurance evaluation. Motivation to return to work may be impacted by economic and nonclinical factors. Evaluators should delineate symptoms that create impairment from factors, when present, affecting motivation or treatment.

The written report should reflect the nature of the referral, the history obtained, opinions listed as responses to the referral questions, and the bases for opinions (Gold and Shuman 2009; Anfang and Wall 2011). If there is insufficient information to provide an opinion, the IME psychiatrist should suggest what additional information would be required to provide an opinion (i.e., additional records, psychological testing, etc.).

IME psychiatrists should limit their opinions to those requested and should use the definition of disability supplied by the referral source. Sometimes a relevant and significant issue may be discovered in the course of the evaluation, and may require discussion even if no specific referral question addresses that issue. For example, if the psychiatrist finds that an individual whose disability claim is based on depression also has a substance use disorder of which the treating clinicians are unaware, the IME psychiatrist should raise this issue in the report.

Some referral sources provide a format for the written report, and psychiatrists should adhere to the requested format. IME psychiatrists should expect that other parties besides the referral source will review their reports, including the claimants themselves, their treating clinicians, and the claimants' attorneys. Examiners should always write reports using appropriate clinical language and avoid making judgmental or pejorative statements.

WORKERS' COMPENSATION

All states have workers' compensation programs, each differing in statutory requirements, case law, and administrative

practices. Most federal employees are covered under the Federal Employees' Compensation Act, administered through the U.S. Department of Labor, Office of Workers' Compensation Programs.

Workers' compensation programs were intended to provide timely and efficient compensation to injured workers for work-related injuries while controlling employer's costs. These statutes represented a compromise, under which disabled employees receive a certain percentage of wages during the period of disability and medical care at the employer's (insurer's) expense, and the employer is liable only for limited and statutorily set awards. Workers' compensation is an exclusive remedy: claimants cannot make tort law claims regarding the same injuries. However, employers cannot utilize previously established defenses against liability such as contributory negligence or assumption of risk (Gold and Shuman 2009; Drukteinis 2011).

Eligibility for workers' compensation is determined by establishing a nexus between the injury and the employment. The worker only needs to show that the injury was the result of a work-related event. Generally, the injury must arise "out of and in the course of employment." This means that the employee was exposed to a risk in the place of employment greater than that encountered in everyday life and injury must have occurred within the time and place of employment (Warshaw 1988).

The American Medical Association's (AMA) *Guides to the Evaluation of Permanent Impairment* (AMA 2007) and state law provide definitions of relevant terms for psychiatrists involved in workers' compensation evaluations. Approximately 40 states and most federal workers' compensation programs either require or rely on the AMA's *Guides* to assess issues relevant to disability, although not all use the *Guides* in the same way or even require use of the most recent edition (Moss et al. 2012). However, programs typically share certain features:

1. Employees required to participate in workers' compensation program are entitled to benefits when they suffer an injury by accident arising out of and in the course of employment or occupational disease.
2. Negligence and fault are largely immaterial to the validity of a claim or the amount to which the claimant is entitled.
3. Benefits include cash-wage benefits, usually around one-half to two-thirds of the employee's average weekly wage, and hospital, medical, and rehabilitation expenses.
4. Employees and their dependents give up their right to sue the employer for damages for any injury covered by the workers' compensation program.
5. Rules of procedure and evidence are relaxed in the evaluation and adjudication of claims (Larson and Larson 2008).

Additionally, when psychiatric injury is claimed, claimants must demonstrate that they were placed at increased risk for exacerbation or injury, or that stress or trauma precipitated the effects of the condition (Larson and Larson 2008).

Differences between workers' compensation and other disability insurance systems

Tort law and workers' compensation differ with regard to liability, the nature of the injuries compensated, and the amount of compensation. Under tort law, liability is demonstrated by proving direct causation; under workers' compensation, liability is determined by the relationship of the injury to the workplace. Compensation in tort law is intended to restore that which the claimant has lost. In contrast, workers' compensation benefits tend to be statutorily fixed, modest, and time limited. Unlike SSDI, workers' compensation benefits may be awarded for disability that is partial or total, and temporary or permanent. Finally, pain and suffering, while compensable under tort law, are not compensable under workers' compensation (Gold and Shuman 2009; Drukteinis 2011).

Psychiatric claims in workers' compensation

Initially, workers' compensation statutes essentially excluded disability benefits for mental conditions (Tucker 2010). Concerns regarding the validity of claims of mental injury or trauma leading to a mental disorder have led many states to approach such claims by categorizing them as

1. Physical–mental injury claims
2. Mental–physical injury claims
3. Mental–mental injury claims

PHYSICAL–MENTAL AND MENTAL–PHYSICAL INJURY CLAIMS

Even after mental conditions became more widely recognized, they were required to have a physical connection. Physical injury leading to a mental disorder (i.e., physical–mental claim) and mental trauma leading to a physical disorder (i.e., mental–physical claim) reflect this concept (Larson and Larson 2008). All states allow claims for physical injuries that cause mental disorders and claims for injuries due to mental disorders that cause physical disorders.

In a mental–physical claim, stress or an emotional problem is claimed to have led to an objectively measured physical disorder, such as stress leading to heart attack (Larson and Larson 2008). In a physical–mental claim, a physical injury is alleged to have led to an emotional injury. An example of such a claim would be that of a firefighter who is burned in the course of duty, but whose impairments and subsequent disability result primarily from posttraumatic stress disorder rather than from physical problems.

MENTAL–MENTAL CLAIMS

The most controversial category of stress claim is the mental–mental claim: a claim that a psychological trauma has caused a psychiatric disorder (Gold and Shuman 2009; Tucker 2010; Drukteinis 2011). The most straightforward mental–mental claims are psychiatric disorders caused by an obvious traumatic event or limited sequence of events, such as a fire at a plant or a bank robbery (Gold and Shuman 2009; Drukteinis 2011). In contrast, attempts to evaluate the cumulative effects of exposure to work-related stress present a more difficult challenge. *Carter v. General Motors* (1960) established the legitimacy of an occupational stress claim under a workers' compensation statute.

Mental injury that results from a single or limited sequence of events, such as a fire, may be easier to identify as traumatic and potentially damaging. In contrast, chronic stress caused by a harsh supervisor resulting in depression is difficult to assess objectively. Moreover, even where mental–mental claims are allowed, statutory language frequently requires that such claims entail more than "ordinary" workplace stress, which all employees are assumed to experience (Drukteinis 2011).

Some jurisdictions have relaxed the realm of compensable emotional injury to include prolonged or cumulative work stress, and there has been a trend to compensate for many conditions, such as gastric ulcers, that are claimed to result from such stress (Gold and Shuman 2009). Some states still compensate mental injury leading to physical injury only when it can be traced to a specific traumatic workplace event. Because mental–mental claims are more difficult to demonstrate convincingly, recovery for them is limited (Lasky 1993; Larson and Larson 2008).

Psychiatric opinions in workers' compensation

One of the most common areas of dispute in workers' compensation claims is "causation," specifically, whether the mental disorder arose out of and in the course of employment. Absent a circumscribed traumatic event, the task of demonstrating a causal nexus to the workplace may be complicated by pre-existing mental disorders and other sources of stress in the claimant's life. A causal relationship between the workplace and the resulting psychiatric injury is more likely when the injury is severe and pre-existing psychiatric disorders or symptoms are few or absent (Gold and Shuman 2009; Drukteinis 2011).

Workers' compensation laws also recognize that exacerbation of a pre-existing injury can be causally related to the workplace. Psychiatrists may be asked to address apportionment to pre-existing disorders or other causes of impairment and disability (Larson and Larson 2008). Additionally, workers' compensation statutes specify four "subcategories" of disability that combine the evaluation of impairment with a prognostic assessment: temporary–partial, temporary–total, permanent–partial, and permanent–total. These categories are used to project loss and assess the benefit amount.

Under workers' compensation statutes, permanent disability benefits begin after the worker has reached maximum medical improvement (MMI) and has received an impairment rating. MMI generally means that the underlying condition causing disability has become stable and further medical treatment will not improve the condition, although treatment may still be needed to prevent further deterioration.

Psychiatric evaluation in workers' compensation

Psychiatrists are typically asked to provide opinions regarding one or more of the following questions (Brodsky 1987; Lasky 1993; Gold and Shuman 2009; Drukteinis 2011):

1. Does the claimant have a psychiatric disorder, and if so, what are the symptoms and the duration of the disorder?
2. Is the psychiatric disorder disabling, and if so, what are the functional impairments and how are they related to the claimant's occupation?
3. Was the psychiatric disorder caused by the workplace, and if so, how?
4. Is there apportionment to pre-existing disability or factors other than the workplace?
5. Is treatment indicated, and if so, what type, duration, and frequency?
6. What is the prognosis and duration of required treatment?
7. If treatment has been rendered, was it appropriate, considering type, duration, and frequency?
8. Would the claimant benefit from additional types of treatment, such as occupational or vocational rehabilitation treatment?
9. Has the claimant reached MMI? If not, when might the claimant reach MMI?
10. Is the claimant's disability temporary–partial, temporary–total, permanent–partial, or permanent–total?
11. Can the claimant return to the workplace, and if so, when?
12. If the claimant can return to the workplace, are limitations present or are restrictions recommended?

Psychiatrists should conduct a standard psychiatric examination with emphasis on issues pertinent to the referral questions. Psychiatrists should be familiar with the language in the state or federal statutes that applies to the case at hand and address their inquiries and opinions to the standards articulated by that language. Relevant medical, mental health, employment records, and performance evaluations should be reviewed. If the case is in litigation, psychiatrists should review legal complaints, depositions, responses to interrogatories, and investigative reports that often include statements from past employers, coworkers, and supervisors. Relevant legal history may also include any past arrests and prior litigation. Collateral sources of

information will assist in the assessment of potential exaggeration, minimization, or malingering.

Evaluating psychiatrists should obtain an occupational history including a detailed work history both before and after the claimed injury, an assessment of pre-existing conditions, a summary of prior job experiences, whether the claimant has filed other workers' compensation or disability claims, and information about the evaluee's future plans for work. Emphasis should be placed on the worker's experience with the medical care system and the workers' compensation system due to issues related to entitlement and secondary gain. Depending on the opinions requested and the relevant jurisdictional statutes, psychiatrists may also need to provide a disability rating or percentage. If so, evaluating psychiatrists should utilize the statutorily prescribed rating system.

Generally speaking, a three-part analysis is used to adjudicate eligibility for benefits under workers' compensation:

1. The existence of a psychiatric disability that prevents work
2. That the disability is caused by psychiatric injuries
3. That the psychiatric injuries are work related (London et al. 1988)

The findings of the psychiatric evaluation should be presented in a written report that addresses these issues and should also provide specific answers to referral questions utilizing statutorily defined terms and ratings.

FITNESS-FOR-DUTY EVALUATIONS

The central purpose of a fitness-for-duty (FFD) evaluation is to determine whether employees whose psychological status is perceived as potentially unstable or threatening in some way that affects job performance or safety are able to safely and effectively perform their jobs. Concerns may involve performance issues or changes in behavior that are perceived to endanger the employee, coworkers, or the public. Evaluating clinicians should have a clear understanding of what event(s) precipitated the FFD referral, the employee's job requirements, and the employer's concerns.

Administrative and legal regulation of FFD evaluations

A variety of systems are in place to ensure continuing competence in safety-related occupations. Administrative bodies such as state medical review boards generally have a system of rules, including standards regarding job-related impairments and actions that may be taken if impairments are suspected or reported (Stone 2000). FFD evaluations are frequently mandatory if employees want to maintain licensure or continued employment.

Employees are potential vicarious liabilities for their employers (Schouten 2008). Employers are expected to monitor their employees' behavior and mental status, and they are required to intervene appropriately when that employee's performance or health status has reached a threshold of serious threat to the employee, others, or public safety. Employers are required to take steps to increase the probability that a workplace is protected from the danger presented by employees who have become unstable.

To meet the legal threshold for requiring an employee to undergo an FFD examination, an employer's referral should be based on the presence of both job-related performance or safety issues and an employee's known or suspected mental impairment. An individual with a mental impairment but no job-related performance or risk issues, or an individual with job-related performance or safety issues but without a known or suspected mental impairment, is not appropriate for a FFD evaluation (Stone 2000).

The psychiatric FFD evaluation referral

Referral sources often ask evaluators to complete FFD assessments on an urgent or emergent basis, and the need for a psychiatric FFD evaluation, particularly if a threat of violence is involved, may seem acute for both employee and employer. However, these complex assessments generally cannot be completed quickly for a variety of reasons, including the time required to obtain and review relevant documentation. Psychiatrists should carefully assess the appropriateness of the referral. Employees in a mental health crisis may require an emergency clinical assessment, often in an emergency room setting for safety purposes (Gold and Shuman 2009; Pinals and Price 2011; Wettstein 2011; Schouten 2011).

An independent evaluation is almost always necessary to address relevant forensic and treatment issues in FFD evaluations. Dual-agency relationships in FFD evaluations generally create insurmountable ethical, legal, and boundary problems. Additionally, individuals in occupations that impact public safety are subject to special scrutiny if they display poor judgment, signs of cognitive impairment, or disruptive behavior. They are also usually subject to higher standards of functioning to meet fitness requirements. FFD evaluations involving highly specialized or public safety jobs, such as those associated with weapons-carrying positions, often require forensically trained evaluators with additional expertise.

Informed consent

Prior to conducting the FFD evaluation, psychiatrists and referral sources should discuss the scope of evaluation, the inquiries that are permissible, and access to the FFD report, any of which might be limited by statute, policy, or contractual provisions. The evaluee should review and demonstrate understanding of these issues. Confidentiality issues are particularly complex in FFD evaluations due to the relationship between FFD evaluations and the workplace. Obtaining informed consent in writing, including the evaluating psychiatrist's role, a review of referral issues,

the limits of confidentiality, and to whom the report will be forwarded, is essential (Gold et al. 2008; Gold and Shuman 2009). If the evaluee is unwilling to give informed consent for the evaluation, the evaluating psychiatrist should not proceed (Gold and Shuman 2009).

The psychiatric fitness-for-duty clinical examination

The FFD psychiatric examination should seek only information necessary to determine whether the employee can perform the job safely or presents a threat to self, others, or the public; if the employee cannot perform the job safely, are these occupational problems related to psychiatric illness? Prior to the clinical interview, psychiatrists should obtain a referral letter describing the work problems and stating the requested opinions. Documents provided for review should be relevant to issues of job performance, including a job description, safety, and psychiatric illness, and should include documentation of the concerns that have resulted in the evaluation.

In addition to the standard elements of a comprehensive psychiatric evaluation, evaluees should be encouraged to provide their perspective of the events leading to the FFD (Meyer and Price 2012). Evaluators should ask specific questions about the referral issues. Although some evaluees become angry when questioned, more often they want to explain why the employer's concerns are valid or invalid, and what may have led to misinterpretation or distortions in the reports of their behavior or functioning. These responses provide needed information regarding the evaluee's impulse control, cognition, insight, and judgment.

Finally, risk assessment and risk mitigation are an important part of all referrals for disruptive, threatening, or dangerous behavior. Evaluators should address any reported safety or danger concerns directly with the evaluee. Static and dynamic factors that indicate heightened risk of violence, if present, should be reviewed and discussed.

FFD evaluees frequently minimize psychiatric symptoms or impairments in order to return to the workplace. Minimization of symptoms may be due to lack of insight, denial, or intentional dissimulation. Psychiatrists should note and record discrepancies between the evaluees' report and those of the referral and collateral sources, as well as internal inconsistencies in the accounts of behavior, symptoms, or concerns.

The FFD report

A psychiatric FFD report should be limited to relevant job-related issues (Anfang et al. 2005; Gold et al. 2008; Pinals and Price 2011; Wettstein 2011). Psychiatric FFD reports typically provide opinions about the presence (or absence) of a psychiatric illness, and the extent, if any, to which the illness has interfered with the evaluee's ability to function effectively and safely in the specific work setting. Psychiatrists should describe how the mental illness affects job-related capacities and provide specific examples of impairments, including insight and judgment. The foundation for opinions should be discussed in detail in the report. If evaluators feel they do not have enough information to come to an opinion because of deficient documentation or lack of cooperation, the report should reflect these issues and what would be needed to reach an opinion.

If evaluating psychiatrists conclude that the evaluee has no psychiatric disorders or impairments that prevent return to the workplace, they should demonstrate that they understand the reasons that prompted the referral (Anfang et al. 2005; Anfang and Wall 2006). If such an evaluee presents ongoing safety or performance concerns in the workplace, employers or regulatory agencies will need to address these administratively. Alternatively, if evaluating psychiatrists conclude that a psychiatric disorder has caused an evaluee to become unfit for duty, this conclusion should be accompanied by supporting data relating symptoms to occupational impairments. FFD evaluations where dangerousness in the workplace or concerns of public safety has arisen also usually require an assessment of short- and long-term risk and suggestions for risk management.

PERSONAL INJURY

Historically, personal injury litigation has involved claims for damages caused by physical injuries. Courts have long recognized that psychological injuries often accompany physical injuries. When a causal connection between the physical and psychological injuries has been shown, damages for both types of injuries are recoverable.

Courts (and legislatures) have been more reluctant to compensate plaintiffs for mental suffering alone, because such claims are difficult to prove and distinguishing between serious emotional injury and feigned or exaggerated claims is often difficult. However, most states now recognize such claims.

When a person purposefully or recklessly engages in conduct with the intent of causing severe emotional distress, the claim is Intentional Infliction of Emotional Distress, also known as Outrageous Conduct. The conduct can be verbal (oral or written) or nonverbal, e.g., intending to induce panic by seemingly trying to run someone over. The common law in all states recognizes some form of the tort of Outrageous Conduct, and 23 states allow verbal conduct alone as sufficient, although verbal statements typically must be of sufficient virulence or offensiveness to be actionable (DiSabatino 2014). Outrageous Conduct is usually an ancillary claim to a primary claim, which is typically also an intentional tort, such as racial discrimination, defamation, or assault. Outrageous Conduct is rarely the only claim, because such claims can be viewed with suspicion by jurors, and causation and damages can be difficult to prove.

Recently, claims of cyberbullying or revenge porn have led to Outrageous Conduct litigation, as well as invasion of privacy or defamation. Due to highly publicized cases involving teen suicide, some states are considering whether

to criminalize the misuse of social media, especially when minors are targeted (see, e.g., Colorado House Bill 14-1131, 2014).

As with other intentional torts, if the plaintiff can prove severe emotional distress, monetary damages including reasonable treatment costs are recoverable. Under the "thin skull" (or "eggshell") rule, if the plaintiff has pre-existing vulnerability, all damages are still usually recoverable. If the defendant is aware of the plaintiff's status and deliberately undertakes to exploit it, punitive damages may also be recoverable.

A less common claim is Negligent Infliction of Emotional Distress, where the victim is not specifically the "target" of the outrageous behavior but nonetheless experiences severe emotional distress as a result of offensive behavior directed toward another. This is sometimes referred to as "bystander" recovery. For example, if a mother witnesses her child killed in a crosswalk by a speeding driver, the mother may suffer severe emotional distress. In order to impose liability under such circumstances, courts construct a legal "duty" to act appropriately, then impose that duty on the defendant, then determine the defendant breached that duty with resultant damages to the plaintiff. The case law in this area has developed on a state-by-state basis.

States use one of three primary standards for evaluating claims of bystander recovery: (a) the impact rule, (b) the zone of danger rule, and (c) the foreseeability test (Ginsinger 2014). The impact rule requires the plaintiff bystander to sustain some physical contact or injury in the same accident that injures another. Five states have adopted this standard.

The zone of danger rule does not require physical contact, only proximity. If the plaintiff is close by the injurious event and experiences fear for his or her own safety, recovery is allowed. The proximity requirement entails inherent uncertainty and subjectivity. Ten states presently use this standard.

The most commonly used standard is the foreseeability test. Thirty-one states have adopted this rule, or a variant. In 1968, California first adopted this rule by imposing liability when the negligent defendant should have "foreseen" that his or her conduct would cause psychic injury to a bystander. The factors for imposing liability are (a) the plaintiff is near the scene of the traumatic event that injures another, (b) the plaintiff experiences shock from sensory and contemporaneous observation of the injury (as opposed to learning about it afterward), and (c) the plaintiff is closely related to the victim (*Dillon v. Legg* 1968). Although learning of a violent or accidental injury to a close family member or friend can form a basis for diagnosing PTSD (American Psychiatric Association 2013), the courts are unlikely to expand the criteria for "bystander" recovery in similar fashion.

Once the plaintiff can show liability (under the applicable standard for that jurisdiction), damages for severe emotional distress as well as treatment costs are generally recoverable. However, there are significant differences among the states as to what type and how severe the plaintiff's injuries must be. In addition, the thin skull rule is often rejected for bystander claims in favor of an objective standard, because a victim's idiosyncratic susceptibility or fragility creates difficulty proving causation and weeding out exaggerated claims.

The psychiatric examination for these types of tort claims should address the precipitating event(s), the accuracy and nature of alleged impairments, and whether the claimed impairments are proximately caused by the alleged intentional or negligent conduct at issue. A comprehensive assessment needs to address the following issues (Weissman 1985):

1. The extent to which the accident or exposure caused a new disorder or exacerbated a pre-existing disorder
2. Whether a disorder would have occurred at all but for the instant event(s)
3. The significance to the current disorder of proximate, pre-existing, and coexisting factors
4. The course of a pre-existing disorder with the focus on eventual impairments in the absence of the instant event(s)
5. The role of other factors including malingering, exaggeration, convenient focus, and secondary gain on the current problem(s)

General forensic principles previously described in this chapter apply equally to these evaluations. The medical–legal assessment of a personal injury case generally focuses on identifying the existence of a psychic injury, determining proximate cause, assessing credibility, and assessing prognosis. The nature and degree of impact of the specific event(s) on the life of the plaintiff should be described within the context of a biopsychosocial model (Hoffman and Spiegel 1989). The expert should describe findings and provide diagnostic formulations at a level of probative value. Although the focus and context of the expert opinions differ somewhat from disability examinations and reports summarized in other sections of this chapter, personal injury case reports, comprehensive psychiatric examinations, and ethical principles bear many similarities to those of disability evaluations (Gold et al. 2008).

SUMMARY KEY POINTS

- The Social Security Administration (SSA) administers two disability programs, SSDI and SSI. SSDI provides replacement income for disabled workers, whereas SSI provides a minimum income level for nonworking needy, aged, blind, and disabled persons.
- Psychiatric SSA claims rely primarily on information from treatment providers; initial determinations for eligibility depend on review of documents only.

- If possible, psychiatrists should avoid dual agency—that is, providing disability evaluations for their clinical patients. Dual-agency conflicts may disrupt treatment relationships and bias disability evaluations.
- Independent medical examinations (IMEs) for private disability insurers require a comprehensive psychiatric assessment with a focus on work history and should respond directly to specific referral questions.
- Workers' compensation is an exclusive remedy that provides monetary benefits for injured employees, if that injury is directly and causally related to employment. Psychiatric workers' compensation claims are either physical–mental, mental–physical, or mental–mental.
- Fitness-for-duty evaluations should focus on impairments in occupational functioning due to psychiatric illness. Information provided to employers should be limited to occupational functioning and related psychiatric issues.
- Psychiatrists should obtain informed consent before conducting disability evaluations, personal injury evaluations, or fitness-for-duty evaluations.

Americans with Disabilities Act (ADA) evaluations

PATRICIA R. RECUPERO

INTRODUCTION

The Americans with Disabilities Act was passed by the U.S. Congress in 1990 and affords individuals with disabilities protections against discrimination that are similar to the Civil Rights Act of 1964. It protects against discrimination in a variety of ways, each of which is outlined in one of its Titles (Table 34.1).

Psychiatric evaluations for the Americans with Disabilities Act (ADA) most commonly involve employment cases (Title I). These employment cases are unique among other types of mental health disability evaluations. Often, the evaluee is hoping to remain working, whereas in many other disability assessments the evaluee seeks to establish proof of an inability to work (Gold and Shuman 2009). In the past decade the landscape of ADA evaluations and ADA cases has changed dramatically. The passage of the ADA Amendments Act in 2008 and the release of subsequent guidance from the Equal Employment Opportunity Commission (EEOC) (the agency charged with enforcing Title I of the ADA) have brought significant changes in the definitions and standards involved in ADA cases, particularly with respect to psychiatric disabilities (Regenbogen and Recupero 2012; Recupero and Harms 2013). Title II of the ADA, which covers Public Entities, has also impacted psychiatric practice through cases like *Olmstead v. L.C.* (1999), which protect the civil rights of psychiatrically disabled persons to be free from discrimination. This chapter discusses ADA evaluations in the context of the 2008 Amendments and subsequent EEOC guidance and focuses on Title I employment cases. Readers who plan to conduct ADA evaluations should review the EEOC documents and additional resources on ADA evaluations before agreeing to do so, as this chapter provides only a cursory introduction.

BASIC TERMS

It is important to understand the definitions of several legal terms for the purpose of conducting an ADA evaluation. As an attorney for the EEOC has noted, "practitioners who are aware of the different elements of proof at issue in an ADA case will be better equipped to address those issues, to conduct useful evaluations, and to provide relevant information helpful to employees and employers who seek their services" (Goodman-Delahunty 2000, 202). Because this chapter will refer to these terms throughout the discussion, they will be introduced here.

Impairment and disability

Under the ADA, "[a]n individual is considered to have a 'disability' if s/he has a physical or mental impairment that substantially limits one or more major life activities, has a record of such an impairment, or is regarded as having such an impairment" (EEOC 2008). The impairment does not rise to the level of a disability under the ADA if it does not meet the above requirements. Courts typically recognize most diagnosable disorders as *impairments*, but not necessarily as *disabilities* (Fram 2008).

Major life activity

As noted above, impairment must substantially limit at least one major life activity (MLA) in order for the impairment to be a disability under the ADA. The definition of an MLA has changed in recent years. Currently, the category is broad and includes a wide variety of daily activities. Whether an activity constitutes an MLA under the ADA depends on case law and guidance from the EEOC, which issues rules and opinions regarding the interpretation and implementation of the ADA.

Substantial limitation

To be a disability under the ADA, an impairment's effect on the performance of at least one MLA must be substantially limiting, relative to the general population (Hickox 2011;

Table 34.1 Titles of the Americans with Disabilities Act

Title I	Employment
Title II	Public Entities (including Public Transportation)
Title III	Public Accommodations (and Commercial Facilities)
Title IV	Telecommunications
Title V	Miscellaneous Provisions and Specific Exclusions

EEOC 2011b). This standard has been subject to debate and revision in recent years.

Reasonable accommodation

The ADA requires employers to provide reasonable accommodation to employees or job applicants with disabilities, as long as the accommodation does not pose "undue hardship" to the employer (Gold and Shuman 2009). Failure to provide "reasonable accommodations to the known physical or mental limitations of an otherwise qualified individual with a disability" constitutes discrimination under the ADA (42 U.S.C. §12112(b)(5)(A)). According to the EEOC, "[r]easonable accommodation refers to any change in the work environment or in the way things are customarily done that enables an individual with a disability to enjoy equal employment opportunities" (EEOC 2011a). Whether a particular accommodation is "reasonable" is a complex inquiry and dependent upon numerous factors.

Direct threat

An employer is not required to accommodate an employee if that employee poses a direct threat in the workplace, even if that threat is due to an ADA-related disability. A direct threat is defined as "a significant risk to the health and safety of others that cannot be eliminated by reasonable accommodation" (42 U.S.C. §12111(3)).

Essential job functions

Similarly, an employer is not required to retain an employee who is unable to perform the essential functions of his or her job with reasonable accommodations. Essential job functions (EJFs) are those functions that define the nature of a job but do not include incidental tasks.

DEVELOPMENT OF ADA LAW

Before the passage of the ADA, the rights of disabled persons in the United States were covered by the Rehabilitation Act of 1973, which used the term "handicapped" rather than "disabled" (42 U.S.C.A. §12101 note, September 25, 2008, §2(a)(3)). Under the Rehabilitation Act, courts' interpretations of the term "handicapped" were relatively broad in comparison to subsequent court decisions under the ADA of the 1990s and early 2000s (Center and Imparato 2003; Feldblum et al. 2008).

The ADA used the same definition for "disability" as the definition for a handicapped person under Section 504 of the Rehabilitation Act (Scott 2010). As stated previously, the ADA contains five Titles, but this discussion will focus on Title I, as it covers disability discrimination by private employers and is the most relevant to the majority of ADA evaluations performed by psychiatrists. Title II covers public services and may also be relevant in employment contexts because it applies to certain disciplinary and certification proceedings, such as the Bar in the legal profession and medical licensing boards (Timmons 2005).

Following the ADA's passage, the EEOC published regulations in 1991 for its interpretation and application (EEOC 1991). Subsequent case law significantly narrowed the class of persons who would be considered disabled under the ADA. Beginning in 1999, the U.S. Supreme Court, through a series of cases, further restricted the criteria by which someone could demonstrate that he or she was disabled under the ADA. For example, if one was able to use "mitigating measures" (such as glasses or medication) effectively, such that one's impairment no longer posed a substantial limitation, then one was not considered to be disabled under the ADA (*Albertson's Inc. v. Kirkingburg* 1999; *Murphy v. United Parcel Service, Inc.* 1999; *Sutton v. United Air Lines* 1999). Furthermore, the term "substantially limits" was interpreted to mean "prevents or severely restricts," and MLAs were defined as "activities of central importance to most people's daily lives" (*Toyota Motor Manufacturing v. Williams* 2002). As a result of these rulings, many individuals who had experienced discrimination in the workplace due to their impairments were unable to claim protection under the ADA. Furthermore, physicians treating disabled patients were placed "in the unenviable position of having to show what a patient was unable to do (that he or she was disabled), and then reverse course completely to extensively document that the patient could safely and effectively perform the job in question" (Thomas and Gostin 2009, 96).

Persons with psychiatric disabilities were often caught in what commentators have characterized as a "catch-22": if their disorder was severe enough to cause significant impairment, courts held that they were not qualified to perform the work; if their symptoms were manageable enough that they were able to work, then they were not "disabled" under the ADA and thus were not protected from employment discrimination (Hensel 2002; Center and Imparato 2003). Courts often found that plaintiffs with episodic impairments, such as bipolar disorder requiring temporary hospitalizations, were not sufficiently "disabled" to invoke the ADA's protection (Paetzold 2005). Around the beginning of the twenty-first century, somewhere between 90% and 97% of Title I ADA cases were either dismissed or decided in favor of the defendant employer, typically because the plaintiff was unable to meet the demanding standard for qualifying as "disabled" (Center and Imparato 2003; Ritchie and Zonana 2003; Hickox 2011).

THE ADA AMENDMENTS ACT OF 2008

In 2004, the National Council on Disability published a document criticizing the restrictive Supreme Court holdings and explaining the need to restore the ADA to its original intentions (National Council on Disability 2004). This report helped to speed the efforts of several stakeholders' groups to introduce amendments to the ADA (Feldblum et al. 2008). Efforts to amend and revise the ADA, to restore it to its original intent to protect disabled workers, began as a draft version called the "ADA Restoration Act" (Anderson 2009). The original draft was deemed by some commentators to contain too broad a protected class, and a revised set of amendments was developed with participation by civil rights activists, members of the disability community, and business leaders (Mitka 2008).

The Americans with Disabilities Act Amendments Act of 2008 (hereinafter ADAAA) became effective on January 1, 2009 (Pub. L. No. 110-325, 122 Stat. 3553, 2008). Mental health advocates praised the new amendments, predicting that they would rescue people with psychiatric disabilities from the Catch 22 in which the Supreme Court rulings left them. The overall effect of the new amendments was to broaden the class of persons whose impairments would qualify as "disabilities" under the ADA.

Specifically, the ADAAA implemented the following changes: (1) expanded the definition of MLAs, and a list of some examples of recognized MLAs was provided; (2) explicitly rejected the Supreme Court's holdings in *Sutton v. United Air Lines, Inc.* (1999) and *Toyota Motor Manufacturing v. Williams* (2002) as too restrictive; (3) broadened the class of individuals who were protected under the "regarded as" disabled category; and (4) clarified that employers need not provide accommodation for employees who are merely "regarded as" disabled but who are not, in fact, disabled (Fram 2008). The ADAAA also called for revision of the original EEOC guidelines in order to capture a broader class of disabled persons. The amendments emphasize that "[t]he definition of disability in this Act shall be construed in favor of broad coverage of individuals under this Act, to the maximum extent permitted by the terms of this Act" (42 U.S.C.A. §12101 note, September 25, 2008, §4(a)). In this respect, the ADAAA marked a return to a less restrictive standard for coverage like that of the Rehabilitation Act (Feldblum et al. 2008). Clinicians who conducted ADA evaluations prior to the passage of the ADAAA of 2008 may be familiar with the term "qualified individual with a disability"; however, the ADAAA removed this term from most of Title I, and the EEOC reduced use of the term as well in subsequent regulations (EEOC 2011b). Nonetheless, the *concept* is still relevant; a disabled person is not entitled to a particular job merely by nature of being disabled—one must still be qualified for the position, with or without reasonable accommodations.

The ADAAA specifically states that certain aspects of the EEOC's original ADA regulations were inconsistent with the congressional intent in enacting the ADA; consequently, the amendments directed the EEOC to revise the regulations (Siber 2009). The EEOC's final regulations (EEOC 2011b) were published in 2011, and psychiatrists who perform ADA evaluations today might find them helpful. Whereas the status of mental illness under the original ADA was often controversial, the final regulations stress that the ADAAA is intended to provide protection for persons with psychiatric disabilities (29 C.F.R. §1630 [Appendix]) (EEOC 2011b).

ADA EVALUATIONS AND PSYCHIATRIC DISABILITIES

Performing an ADA evaluation of a person with a psychiatric disorder can be a complicated process. The psychiatrist may be retained by an attorney for an employee–plaintiff in a discrimination lawsuit against an employer, but retention in the pre-litigation stage is also common (Gold and Shuman 2009). The purpose of the evaluation varies depending on the context. If serving as an expert witness, the forensic psychiatrist's role may be to determine whether the individual has an impairment, to assess and document the severity and impact of that impairment on the performance of major life activities (MLAs) and essential job functions (EJFs), and to offer information about treatment options and how they may affect work performance and prognosis. Alternative dispute resolution, such as mediation or arbitration, is common and encouraged in ADA cases, as it can minimize stress and cost for both sides in a dispute (Ritchie and Zonana 2003; Hickox 2011). In such cases, the psychiatrist's focus may be on helping the employer and employee to strategize possible accommodations for the disability. A mental health professional may also be asked to perform an evaluation or provide documentation and information about the nature of a claimed psychiatric disability, as well as any associated functional impairments, to an employer when an employee or job applicant discloses a disability and need for accommodation (EEOC 1997).

Establishing that an evaluee has an *impairment* may be as simple as determining that he or she has a diagnosable disorder of some kind. Under the ADAAA, the disorder need not be incapacitating in order to be deemed a disability. The EEOC specifically mentions conditions such as autism, major depressive disorder, bipolar disorder, posttraumatic stress disorder, obsessive–compulsive disorder, and schizophrenia as impairments that should easily meet the disability standard of substantial limitation in at least one MLA (EEOC 2011b). However, the ADA also specifically excludes certain diagnoses from coverage, including "various sexual behavior disorders, compulsive gambling, kleptomania, pyromania, and psychoactive substance use disorders resulting from current illegal use of drugs" (EEOC 1997). However, the individualized inquiry in an ADA evaluation is far more nuanced and complex than the mere question of whether an evaluee has a diagnosable disorder (Ritchie and Zonana 2003).

MAJOR LIFE ACTIVITIES (MLAs) AND ACTIVITIES OF DAILY LIVING (ADLs)

Under the newly amended ADA: "[M]ajor life activities include, but are not limited to, caring for oneself, performing manual tasks, seeing, hearing, eating, sleeping, walking, standing, lifting, bending, speaking, breathing, learning, reading, concentrating, thinking, communicating, and working… [A] major life activity also includes the operation of a major bodily function, including but not limited to, functions of the immune system, normal cell growth, digestive, bowel, bladder, neurological, brain, respiratory, circulatory, endocrine, and reproductive functions" (42 U.S.C.A. §12101 note, September 25, 2008, §4(a)). The lists are not intended to be exhaustive (Scott 2010). Under the ADAAA and the EEOC's final regulations, an activity does not have to be "of central importance to daily life" in order to be considered an MLA (Hickox 2011).

The EEOC has also provided guidance regarding what activities qualify as MLAs among persons with psychiatric or mental impairments:

> The major life activities limited by mental impairments differ from person to person. There is no exhaustive list of major life activities. For some people, mental impairments restrict major life activities such as learning, thinking, concentrating, interacting with others, caring for oneself, speaking, performing manual tasks, or working. Sleeping is also a major life activity that may be limited by mental impairments. (EEOC 1997)

Psychiatrists may recognize some similarities between the legal concept of MLAs and the clinical concept of activities of daily living (ADLs). Although the terms are not synonymous, understanding a disorder's impact on ADLs in a clinical sense "can provide a helpful starting point for an assessment of limitation in different MLAs" (Recupero and Harms 2013, 265). Through the final regulations (EEOC 2011b) as well as an earlier document about psychiatric disabilities (EEOC 1997), the EEOC has provided some guidance on evaluating MLAs in the context of mental illness.

Several possible MLAs to consider in the evaluation of a worker with a psychiatric disorder may include interacting with others, cognitive functions (such as thinking, concentrating, and learning), caring for oneself, sleeping, performing manual tasks, and communicating (Recupero and Harms 2013). Among these activities, there has been some controversy regarding the status of "interacting with others" as an MLA under the ADA (Hensel 2002; Hartman 2005). Some commentators had requested that the EEOC remove the term "interacting with others" from the list of MLAs in the post-ADAAA regulations, but the EEOC's final regulations retained the term as an example of a MLA (EEOC 2011b). Although employers might be concerned that persons with personality or character flaws (such as an argumentative or confrontational nature) might cite difficulty in "interacting with others" as *ipso facto* evidence of a disability, the ADAAA's intent was not to excuse workplace misconduct. As the EEOC notes:

> The definition of an impairment also does not include common personality traits such as poor judgment or a quick temper where these are not symptoms of a mental or psychological disorder. (EEOC 2011b, 17007)

EVALUATING AND DOCUMENTING SUBSTANTIAL LIMITATION

In an ADA evaluation, one of the psychiatrist's chief responsibilities is to assess and document the evaluee's level of functional impairment. Although not specifically required by the Supreme Court, legal scholars have suggested that expert medical testimony may be necessary in order to establish "substantial limitation" in post-ADAAA cases (Hickox 2011). The ADAAA specifies that, with the exception of eyeglasses, impairments should be considered in the absence of mitigating measures (42 U.S.C.A. §12101 note, September 25, 2008, §4(a)). Thus, to assess the severity of a person's impairment, the psychiatrist should assess the evaluee's level of functioning when a disorder is in its untreated form. However, it will often be necessary to provide information about an evaluee's expected level of functioning *with* mitigating measures such as psychotropic medication or psychotherapy. This latter inquiry is relevant to establishing whether an evaluee is able to perform the EJFs of the job in question, with or without reasonable accommodation.

Under the ADAAA and the new EEOC regulations, substantial limitation is a lower standard than previously required by courts under the original ADA:

> The term "substantially limits" is defined as "materially restricts" which is intended, on a severity spectrum, to refer to something that is less than "severely restricts," and less than "significantly restricts," but more serious than a moderate impairment which is in the middle of the spectrum. (Feldblum et al. 2008, 236)

The restriction imposed by a limitation need not be severe or outwardly obvious to casual observers in order to invoke ADA protection. For example, in *Overton v. Reilly* (1992), a chemist with depression objected to a new policy that would require him to have regular contact with the public. Although Overton's outward behavior may not have been perceived by others as pathological or problematic, his internal struggle and subtle psychiatric consequences of his disability were nonetheless significant. There are, however, cases in which an employee's disorder manifests as behavior or conduct that is noticeable and problematic in

the workplace. In *Ray v. Kroger Co.* (2003), a grocery store employee with Tourette's syndrome was terminated after inappropriate outbursts and racial slurs in the workplace.

The evaluation of functional impairments for an ADA evaluation is otherwise similar to the assessment of functional impairment for other types of disability (see Chapter 31, this volume). When assessing limitations and functional impairments for an ADA case, the psychiatrist should consider whether, and how, a particular disorder or symptom cluster "materially restricts" the performance of one or more MLAs. The EEOC indicates that the evaluator may consider the nature and severity, expected duration, and long-term impact of a limitation in order to determine whether it is "substantial" (EEOC 2011b).

JOB DESCRIPTIONS AND EJFs

In all work-related disability evaluations, it is advisable to obtain a copy of the job description in question (Gold et al. 2008). The job description should list the major EJFs for the position in question. After performing a diagnostic evaluation, the psychiatrist may go through the EJFs one by one, analyzing the potential impact that the evaluee's disorder (and its treatment) may have on his or her performance of each EJF. Past job performance evaluations and an evaluee's vocational and educational history can also provide helpful information regarding an employee's ability to safely and effectively perform the EJFs of a position. When written job descriptions are brief and provide little information about the position, the psychiatrist may need to obtain further information from the employer, the evaluee, or other relevant parties.

In some cases, the evaluee's limitations in specific MLAs (e.g., impairment in interacting with others due to social anxiety or flat affect) may have some bearing on his or her ability to perform specific EJFs (e.g., cold-calling in sales jobs, contract negotiations, etc.). An evaluee's profession may also provide starting points for the evaluation of impairments or abilities in the performance of basic EJFs, such as the core competencies required in medicine (Regenbogen and Recupero 2012). The EEOC also provides guidance for the application of the ADA to specific professions; their resource document on reasonable accommodations for attorneys with disabilities, for example, has a wealth of helpful information that is applicable to a number of other fields and careers (EEOC 2011a).

A somewhat recent case that forensic psychiatrists should find informative is that of *Jakubowski v. The Christ Hospital, Inc.* (2010), in which a family medicine resident with autism spectrum disorder (Asperger disorder) sued his training program for being terminated due to errors and severe impairments linked to his disability. Although the resident was easily able to demonstrate that he was disabled, he was *not* able to demonstrate that he was otherwise qualified for his position as a family medicine resident. His deficiencies resulted in an inability to perform the EJFs of a resident in family medicine, and he had rejected the training program's attempts to accommodate his impairment by transitioning to a different medical specialty.

REASONABLE ACCOMMODATION

Depending on the context of the evaluation, the psychiatrist may be asked to provide recommendations of possible reasonable accommodations for the employer to consider. Although the employee bears the responsibility for disclosing the need for accommodation (Matejkovic and Matejkovic 2008/2009) and proposing an initial accommodation (*McKane v. UBS* 2010), the employer must engage in a meaningful interactive process to provide reasonable accommodation to the disabled employee (*EEOC v. Chevron Phillips* 2009; Valderrama 2010; Collins and Phillips 2011). The employee who discloses a disability and need for accommodation can make the request in plain English and need not use the phrase "reasonable accommodation" (EEOC 1997). Several cases have held that the submission of a note from a physician suggesting a change, e.g., transfer to a less stressful position, constitutes a request for accommodation (EEOC 1997; Gold and Shuman 2009). In some cases, impaired insight or judgment or other factors (such as severe social anxiety) may prevent an employee or job applicant from disclosing the need for accommodation until serious problems have arisen (Foote 2003). Unfortunately, the employee or applicant in such a case is not likely to succeed in an ADA suit; an employer is not required to provide accommodation if it is not aware that the employee's limitation requires accommodation.

An employer is not required to provide an accommodation that would pose an undue hardship (Collins and Phillips 2011), or to exempt a disabled employee from the EJFs associated with his or her position (Smith 2006). What constitutes an "undue hardship" varies from case to case, but often accommodations for employees with psychiatric disabilities are inexpensive and easily managed by the employer. Furthermore the EEOC, noting published research on this subject, has estimated that roughly half of requested accommodations have zero cost to the employer (EEOC 2011b). When considering options that have equivalent benefit or protection for the employee, the employer is usually free to select the accommodation carrying the least inconvenience or cost (Ritchie and Zonana 2003). The forensic mental health evaluator, therefore, would be well advised to consider suggesting accommodations that pose minimal hardship to the employer while still meeting the employee's or applicant's needs (Gold et al. 2008).

Examples of common accommodations for psychiatric disorders may include use of paid or unpaid leave (e.g., FMLA leave) for inpatient treatment or outpatient therapy appointments; a modified schedule to allow the employee to see a psychiatrist during the week; allowing the employee to come in to work later in order to minimize the impact of medications that cause somnolence; physical changes to the work environment to minimize distractions; policy changes, such as allowing frequent shorter breaks or allowing the use of headphones; providing a job coach or access to an Employee Assistance Program counselor during the work day; switching a position to part-time hours; or transferring the employee to a job better suited to his or her skills

and needs, as long as that does not pose an undue hardship to the employer (Gold and Shuman 2009; Recupero and Harms 2013).

Organizations and resources such as the Job Accommodation Network (http://askjan.org/) and the documents available on the EEOC's website (http://www.eeoc.gov/) can help the psychiatrist, employer, and evaluee to learn more about possible accommodations that have worked for other employees. In formulating recommendations for specific accommodations, the mental health professional should be careful to provide a rational explanation for why and how a particular accommodation would be helpful (Ritchie and Zonana 2003). Courts have held that merely providing a list of possible accommodations, without explanation of why and how such accommodations would be helpful, is insufficient (Gold and Shuman 2009). Concerning post-ADAAA changes, the EEOC suggests that "accommodations such as break times, reduced hours, or job redesign … are the more likely accommodations to be requested by those individuals whose coverage [under the ADA] has now been clarified [by the ADAAA]" (EEOC 2011b, 16992).

EVALUATION OF A DIRECT THREAT

The mental health evaluator may need to determine whether an employee's condition poses a direct threat in the workplace. This determination must be context specific. For example, a school bus driver may pose a direct threat if his or her condition requires treatment by medications that cause slowed reaction time or marked drowsiness. As other scholars have noted, the threshold for posing a direct threat may be lower in certain occupations (e.g., airline pilot) (Ritchie and Zonana 2003; Gold and Shuman 2009), and in such cases the employee may bear the responsibility for demonstrating that he or she does not pose a direct threat, once the direct threat issue has been raised (Collins and Phillips 2011). However, coworkers' or employers' irrational fears of mental illness are insufficient to demonstrate that an employee poses a direct threat. The psychiatrist's report or testimony may help to clarify that an employee's illness does not represent a direct threat (Smith 2007). The EEOC has offered detailed guidance on evaluating "direct threat" in persons with psychiatric disorders (EEOC 1997).

The case of *Jarvis v. Potter* (2007) concerned an employee whose symptoms of posttraumatic stress disorder were held to pose a direct threat that could not be accommodated in the workplace (Teitelbaum and Thomas 2009). The plaintiff was terminated from a job at the U.S. Postal Service after three incidents in which he reacted aggressively to being startled by coworkers; on two of these occasions he had responded with violent behavior toward the coworker. The Tenth Circuit upheld his termination, noting medical evidence that his disorder was chronic and severe and that it might pose a risk in the workplace. Although this case concerned the Vocational Rehabilitation Act and not the ADA, the standards and process for determining a violation are similar.

SUMMARY

Commentators have predicted that the ADAAA of 2008 may have the effect of increasing demand for ADA disability evaluations by forensic mental health professionals (Gold and Shuman 2009; Scott 2010). The observation that "[a] working knowledge of the ADA is increasingly important for mental health providers" (Ritchie and Zonana 2003, 273) is especially accurate in a post-ADAAA world. The performance of an ADA evaluation today may require less time spent in determining whether an evaluee is "disabled" and more time spent assessing the relationships between impairments, EJFs, and various possible accommodations for the evaluee's limitations (Regenbogen and Recupero 2012). Psychiatrists and other mental health professionals who will perform forensic evaluations in ADA cases are encouraged to review additional resources regarding the performance of ADA evaluations, especially guidance from the EEOC.

SUMMARY KEY POINTS

- The Americans with Disabilities Act (ADA) was passed in 1990 and was designed to afford individuals with disabilities protection against discrimination.
- Subsequent case law severely narrowed the class of persons who could be considered disabled under the ADA; persons with psychiatric disabilities had great difficulty proving they were disabled if their symptoms were manageable enough that they were able to work.
- The Americans with Disabilities Act Amendment Act of 2008 (ADAAA) broadened the class of persons whose impairments would qualify as disabilities, and the EEOC has further provided guidance related to mental impairments.
- Psychiatrists performing evaluations under the ADA should quantify impairment, determine how the impairment impacts major life activities, and analyze how the impairment impacts the evaluee's performance of essential job functions (EJFs).
- Finally, psychiatrists may be asked to provide recommendations regarding reasonable accommodations for employers to consider for the disabled employee.

Sexual harassment and gender discrimination

LIZA H. GOLD

INTRODUCTION

Sexual harassment and gender discrimination were non-issues prior to the end of the twentieth century. Media coverage of the Clarence Thomas Supreme Court confirmation hearings in 1991 and other highly publicized sexual harassment claims resulted in a sharp increase in workplace sexual harassment charges and lawsuits (Cunningham and Benavides-Espinoza 2008). Sex-based charges of discrimination filed with the Equal Employment Opportunity Commission (EEOC) and Fair Employment Practices Agencies (FEPA) increased by almost 40% between 1992 and 2012, and monetary awards have increased from $30.7 million to $138.7 million over the same time period. In addition, the percentage of men filing sexual harassment claims has steadily increased over time, from 9.1% in 1992 to 16.3% in 2011 (U.S. Equal Employment Opportunity Commission 2014).

DEFINING SEXUAL HARASSMENT AND GENDER DISCRIMINATION

Legal attempts to address gender disparities in pay and treatment in the workplace, including sexual harassment, began with the Equal Pay Act of 1963, which prohibited sex-based wage discrimination between men and women working for the same employer and performing jobs that require substantially equal skill, effort, and responsibility under similar working conditions. Title VII of the 1964 Civil Rights Act (CRA) prohibits discrimination on the basis of sex, race, color, religion, or national origin and established the EEOC to enforce its statutes.

Illegal sex-based discrimination, including sexual harassment, is not limited to behaviors motivated by sexual attraction or involving sexual activity. In addition, statutes, case law, and the legal system often use the words "sex" and "gender" synonymously, which has created confusion in understanding and identifying illegal behaviors. An individual's sex is a fact of biology; gender is a social construct associated with biological sex, but defined by cultural beliefs, values, and stereotypes. References to illegal "sex-based" discrimination encompass behaviors based on biological sex and on gender constructs associated with either biological sex.

A universally accepted definition of every behavior that might be considered sexual harassment does not exist. Illegal sexual harassment is a subset of all offensive types of gender-based or sexual behavior and a subset of illegal discrimination defined by administrative and case law. Illegal gender discrimination under Title VII of the 1964 CRA can encompass any type of disparate treatment in the workplace on the basis of biological sex: disparities in men's and women's pay for equal work, significant over-representation of men in leadership positions, pregnancy discrimination, and limited occupational choices for men or women. The scope of sexual harassment and gender discrimination behaviors also includes "gender policing," that is, targeting individual men or women for hostile, disparate, and adverse treatment because of failure to conform to gender stereotypes (Anderson 2006; Berdahl 2007).

The EEOC first defined sexual harassment in 1980 as "unwelcome sexual advances, requests for sexual favors, and other verbal or physical conduct of a sexual nature." The EEOC stated this conduct constitutes illegal sexual harassment when

1. Submission to such conduct is made either explicitly or implicitly a term or condition of an individual's employment.
2. Submission to or rejection of such conduct by an individual is used as the basis for employment decisions affecting such individual.
3. Such conduct has the purpose or effect of unreasonably interfering with an individual's work performance or creating an intimidating, hostile, or offensive working environment (EEOC 1980).

The essential component of sexual harassment is "unwelcome conduct" (i.e., conduct that lacks the elements of choice and mutuality) based on sex or gender. If overt or

covert coercion is involved, it typically relies on the power of the perpetrator to affect a target's economic status. Sexual harassment may therefore include forms of gender discrimination that may not be motivated by sexual interest or attraction but that may nevertheless have personal and economic consequences.

The EEOC has defined two types of sexual harassment: *quid pro quo* and hostile environment. "*Quid pro quo*" harassment refers to situations in which work conditions or job benefits are explicitly or implicitly contingent upon or involve the exchange of sexual favors. "Hostile environment" sexual harassment refers to continuous, frequent, or repetitive patterns of offensive and unwelcome behavior that adversely affect the terms or conditions of employment. This category encompasses discrimination on the basis of gender alone, and can include behaviors such as sexually oriented joking or teasing, unwelcome display of sexual images or objects, unwelcome touching or propositions, or hostile treatment based solely on gender.

HISTORY OF SEXUAL HARASSMENT LAW

In *Williams v. Saxbe* (1976), the U.S. District Court for the District of Columbia first established that *quid pro quo* sexual harassment was a form of illegal sexual discrimination under Title VII. The U.S. Supreme Court first considered sexual harassment in *Meritor Savings Bank, FSB v. Vinson* (1986), and established that hostile environment sexual harassment was also a violation of Title VII. The Court stated that to prevail in a hostile environment claim, the behaviors must be so pervasive, repetitive, or severe that they alter the conditions of employment and create an abusive working environment. *Meritor* also established that voluntary participation on the part of the plaintiff did not legally establish that the defendant's actions were welcome.

In *Harris v. Forklift Systems* (1993), the Supreme Court unanimously held that a plaintiff is not required to have suffered psychological harm or prove that she was psychologically injured in order to win monetary damages. The Court stated that the presence of psychological harm is relevant to determining whether the plaintiff found the environment abusive, but is not necessary to establish illegal discrimination. The Court also stated that the frequency and severity of the conduct, whether it was physically threatening or humiliating, and whether it unreasonably interfered with an employee's work performance must be considered in examining sexual harassment claims.

In *Oncale v. Sundowner Offshore Services* (1998), the Supreme Court ruled that same-sex harassment could constitute an illegal form of sex discrimination under Title VII. The Court found that harassing conduct could be motivated by animus or hatred and did not need to be motivated by sexual desire in order to be discriminatory on the basis of sex. In *Burlington Industries, Inc. v. Ellerth* (1998) and *Faragher v. Boca Raton* (1998), the Supreme Court established that if no tangible employment action occurred, an employer might be able to avoid liability or limit damages by demonstrating that

1. The employer exercised reasonable care to prevent and promptly correct any sexually harassing behavior.
2. The plaintiff–employee unreasonably failed to take advantage of preventive or corrective opportunities provided by the employer.

Sex discrimination may also arise from employment actions or policies based on gender stereotypes. In *Price Waterhouse v. Hopkins* (1989), the Supreme Court held that gender stereotyping, in this case resulting in failure to promote a woman due to perceived nonconformity to a female stereotype, constituted a form of sex discrimination. Cases of same-sex harassment of men also have been successfully litigated on the basis of lack of conforming to traditional male stereotypes. In *EEOC v. Boh Brothers Construction Co., LLC* (2012), the Fifth Circuit Court of Appeals held that harassment based on lack of conformity to male gender stereotypes is a form of illegal discrimination.

FILING A SEXUAL HARASSMENT OR GENDER DISCRIMINATION CLAIM

The EEOC enforces federal statutes that prohibit discrimination and retaliation against individuals who have filed good faith complaints or participated in investigatory proceedings. Charges of retaliation, also illegal under Title VII, often form a related but separate basis of action in sexual harassment claims. Title VII requires that a plaintiff must exhaust EEOC administrative remedies for claims of discrimination and retaliation before being granted jurisdiction in federal district court.

After the EEOC investigates a claim, they may attempt to mediate or litigate the complaint. More commonly, the EEOC issues a "right to sue" letter, which allows a claimant to pursue private litigation. Legal action based on sexual harassment or gender discrimination may be brought in one or more legal or administrative contexts including Title VII (federal) complaints, state anti-discrimination laws, workers' compensation claims, and civil tort actions.

In practice, multiple causes of action are common in gender discrimination and sexual harassment cases. The facts of a case may support a variety of legal claims, alone or in conjunction with a Title VII action. The choice of complaint pursued usually involves consideration of issues relating to process, evidentiary requirements, and the recovery of damages. For example, many jurisdictions have laws prohibiting discrimination under Fair Employment Practices (FEP) statutes. Filing a claim under state law may be a more desirable option for someone who wants to expedite proceedings, because state law does not require exhausting EEOC remedies before litigating.

In addition, under federal law, compensatory and punitive damages for Title VII sexual harassment claims are capped at $300,000. Therefore, most Title VII claims

are accompanied by additional claims, such as intentional infliction of emotional distress, or are brought in jurisdictions other than federal court where damages are not capped (Lindemann and Kadue 1992). Regardless of whether evidence of emotional injury is required in order to prevail, plaintiffs typically offer evidence of emotional harm in all types of actions, because the bulk of employer liability and damage awards in harassment and discrimination litigation is related to assertions of emotional distress and psychological injury (McDonald and Kulick 2001). Tort claims that may accompany harassment and discrimination claims include invasion of privacy, defamation, wrongful termination and wrongful discharge, intentional or (more rarely) negligent infliction of emotional distress, civil assault and battery, negligent retention or supervision, and loss of consortium.

PSYCHIATRIC ISSUES IN SEXUAL HARASSMENT CLAIMS

Psychiatrists retained in sexual harassment and gender discrimination cases may be asked to address causation of emotional injury, psychological symptoms and/or diagnoses, related functional impairment, and issues relating to treatment, treatment costs, and prognosis. These evaluations require the identification of psychiatric disorders, present and past level of functioning, and likelihood of recovery. Questions regarding prognosis, with and without treatment, require assessment of the plaintiff's motivation for recovery. Psychiatric factors that may affect claims of causation and damages should also be considered, such as possible alternate causation of claimed emotional distress and pre-existing mental health disorders or problems. Nonpsychiatric factors, such as adverse employment actions and workplace conflict, should also be examined.

A review of all relevant documents and a thorough psychiatric evaluation can provide information relevant to many of the psychiatric and legal issues raised in sexual harassment cases. Forensic experts should be familiar with the social science and psychological research that provides the scientific basis for opinions in sexual harassment and gender discrimination cases. The psychiatric outcome of such workplace experiences depends on multiple factors and circumstances.

A psychiatric evaluation of sexual harassment and gender discrimination claims requires an examination of many factors (Table 35.1). The issues of functional impairment, prognosis, and potential recovery are integral to damage assessments. Current level of impairment is assessed through evaluation of the claimant's history, behavior, and examination findings. The claimant's pre- and post-incident(s) functional capacities must be compared. Prognostic opinions should be based on an assessment of functioning, the effects of pre-existing and current psychiatric status, the natural history of the specific disorder, and the actual or potential effects of treatment.

Table 35.1 Relevant factors for consideration in sexual harassment and gender discrimination claims

Characteristics of the harassment (frequency, duration, magnitude)
Plaintiff's emotional, psychological, and workplace responses to the harassment
If the plaintiff complained, the employer's responses to the complaints and/or harassment
Availability of support for the plaintiff inside and outside the workplace
Plaintiff's resources, strengths, vulnerabilities, and past history
Effects of litigation, widely acknowledged to be stressful (Lenhart 1996; Strasburger 1999)
Emotional effects of retaliation, which may be clinically distinct from the effects of the claimed harassment
Effects of underlying medical conditions or medication that may cause psychological symptoms
Previous or concurrent trauma, sources of stress or distress
Use or abuse of drugs and alcohol
Effects of adverse employment actions or workplace conflict

Comparison of the plaintiff's personality, behavior, and functioning before and after the alleged harassment and discrimination is crucial in the determination of motivation for recovery and willingness to enter treatment (Gold 2004). Motivation to obtain treatment can be particularly problematic in the context of litigation. Plaintiffs are legally obligated to minimize their damages. Nevertheless, plaintiffs often become obsessively focused on legal issues rather than accessing treatment for psychiatric symptoms. In addition, even when plaintiffs obtain treatment, being a party in litigation often prevents resolution of psychiatric symptoms. Symptoms may become fixed and/or exacerbated when litigation becomes acutely stressful, for example, before a deposition or trial.

ASSESSING CLAIMS OF PSYCHIATRIC OR PSYCHOLOGICAL INJURY IN SEXUAL HARASSMENT AND GENDER DISCRIMINATION LITIGATION

Psychiatric evaluations in sexual harassment and gender discrimination cases are informed by research on the psychological effects of sexual harassment experiences, stress and trauma responses, and the legal issues unique to this litigation.

Sexual harassment and gender discrimination research

Social science research has confirmed that sexual harassment and gender discrimination are widespread

phenomena, and has expanded understanding of their causes and outcomes (Fitzgerald et al. 1995; U.S. Merit Systems Protection Board 1995; Dansky and Kilpatrick 1997; Fitzgerald et al. 1997a,b; Fitzgerald et al. 1999a; Gutek and Koss 1996; Kabat-Farr and Cortina 2014). The majority of people reporting sexual harassment experiences are women, and the majority of alleged harassers are men. Women who work in historically male-dominated occupations report higher incidences of sexual harassment (Berdahl 2007).

Broadly speaking, sexual harassment and related forms of gender discrimination fall into three categories, described by three related but conceptually distinct dimensions of behavior (Fitzgerald et al. 1997a):

1. *Gender harassment*: A broad range of verbal behavior, physical acts, and symbolic gestures not aimed at sexual cooperation but which convey insulting, hostile, and degrading attitudes about women. Examples include sexual epithets, slurs, taunts, and gestures, the display or distribution of obscene or pornographic materials, gender-based hazing, and threatening, intimidating or hostile acts.
2. *Unwanted sexual attention*: Both verbal and non-verbal behavior that is unwelcome, offensive, and unreciprocated.
3. *Sexual coercion*: Extortion of sexual cooperation in return for job-related considerations.

Men and women experience different types of behavior as sexual harassment. Same-sex harassment of men by men, regardless of sexual orientation of either party, is typically based on deviation from gender stereotypes (Berdahl et al. 1996; Waldo et al. 1998; Magley et al. 1999; Kabat-Farr and Cortina 2014). Sexual harassment of women usually consists of a cumulative series of escalating and varied experiences causing the target to experience a chronic level of stress and affective arousal, most akin to a particularly noxious form of occupational stress (Fitzgerald et al. 1997b). The less severe forms of sexual harassment behaviors, such as offensive comments or jokes are the most prevalent; the most severe behaviors, such as physical or sexual assault, are the least frequent (U.S. Merit Systems Protection Board 1995; Schneider et al. 1997; Fitzgerald et al. 1999b; Leskinen et al. 2011).

The most common responses to sexual harassment are to ignore or avoid it; the least common response is to formally report it. Although studies consistently find individuals who report experiencing sexual harassment in the workplace, only 5%–30% file formal complaints and less than 1% subsequently participate in litigation (Fitzgerald et al. 1995; Schneider et al. 1997; Wayte et al. 2002; O'Connor 2007).

These social science data are often relevant in sexual harassment litigation. For example, "unwelcome conduct" is an essential element in the legal definition of sexual harassment. Defense attorneys typically interpret failure to immediately report harassment as evidence that the conduct was "not unwelcome," despite the plaintiff's later complaints. In addition, failure to report harassment, as noted above, can provide employers with an affirmative defense, a legal reality at odds with research that indicates failure to report is much more likely than formal reporting, and which may require expert testimony to explain to the finder of fact.

Exposure to sexual harassment can have significant work-related, psychological and physiological effects (Gold 2004; Foote and Goodman-Delahunty 2005; Bowling and Beehr 2006; O'Connor 2007; Street et al. 2007; Dionisi et al. 2012), even harassment that consists primarily of exposure to sexual behavior in the workplace (Berdahl and Aquino 2009). A meta-analysis of 49 studies (Chan et al. 2008) concluded that sexual harassment experiences are adversely related to a multitude of job-related, psychological, and physical outcomes.

The severity of the harassment, as indicated by objective factors such as its frequency and intensity, are primary predictors of psychological outcomes (Charney and Russell 1994; Lenhart 1996; Dansky and Kilpatrick 1997; Schneider et al. 1997; Fitzgerald et al. 1997a; Collinsworth et al. 2009; Rospenda et al. 2009; McGinley et al. 2011). Although even mild harassment can provoke significant emotional distress, women who experienced more severe sexual harassment have been found to have more severe psychological distress, including anxiety and depression. In addition, women who filed a formal complaint or sought legal services were also more likely to experience negative psychological outcomes, negative work-related outcomes, and more somatic symptoms than those who did not (Fitzgerald et al. 1995; Dansky and Kilpatrick 1997; Bergman et al. 2002).

Psychiatric and physiological symptoms caused by sexual harassment may rise to a level of prolonged or intense distress and/or functional impairment that meets criteria for a psychiatric diagnosis. Sexual harassment experiences do not necessarily result in the development of any specific psychiatric disorder. However, psychiatric diagnoses most commonly reported in association with sexual harassment experiences include adjustment disorders, depressive mood disorders, and anxiety disorders (Lenhart 1996; Dansky and Kilpatrick 1997; Gold 2004; Foote and Goodman-Delahunty 2005).

Sexual harassment and posttraumatic stress disorder

Posttraumatic stress disorder (PTSD) is a commonly claimed diagnosis in sexual harassment cases. PTSD is a preferred plaintiff's diagnosis in civil litigation (Gold 2003; Gold 2004), including sexual harassment cases (Long 1994; Gold 2004), because it implies single and external causation and focuses attention on the alleged event(s) rather than the plaintiff. The question of whether sexual harassment can be a form of trauma that may cause PTSD is a matter of continuing debate (Dansky and Kilpatrick 1997; Palmieri and Fitzgerald 2005; Stockdale et al. 2009).

The most common sexual harassment behaviors, such as verbal comments, are relatively minor and rarely traumatic. On the other end of the spectrum, the more uncommon and severe forms of sexual harassment, such as sexual assault, may clearly meet the *Diagnostic and Statistical Manual of Mental Disorders* (American Psychiatric Association 2013) criteria for a traumatic stressor. Questions arise when a plaintiff claims a diagnosis of PTSD directly caused by sexual harassment experiences that fall between these two extremes (Avina and O'Donohue 2002). Although some argue that moderate sexual harassment exposure is also more likely to result in PTSD (Holcomb and Holcomb 2008), a PTSD diagnosis or symptoms are most likely to be associated with more severe and/or more frequent sexual harassment (Dansky and Kilpatrick 1997; Gutek and Done 2001; Street et al. 2007; Stockdale et al. 2009).

Mental health professionals frequently and mistakenly diagnose any stress-related response or symptom as PTSD, particularly in the context of litigation (Rosen 1995). In fact, most people exposed to trauma do not develop PTSD (Kessler et al. 1995; Breslau et al. 1998; Breslau 2009). Exposure to the more common and less severe behaviors associated with sexual harassment can be distressing and stressful but is unlikely to result in the development of PTSD without a pre-existing vulnerability. This is consistent with research findings that indicate vulnerability factors play a significant role in individuals who develop PTSD (Breslau 2009; Raabe and Spengler 2013). An individual who claims or demonstrates symptoms consistent with PTSD as a result of exposure to less severe forms of sexual harassment should be carefully assessed for the possibility of malingering, individual susceptibility to psychiatric morbidity, pre-existing psychiatric disorders, or concurrent or prior traumatic exposure (Gold 2004).

Sexual harassment and personality disorders

Just as PTSD is a preferred plaintiff's diagnosis in sexual harassment litigation, Cluster C Personality Disorders, particularly borderline personality disorder (BPD), is a preferred defense diagnosis (Long 1994). The diagnosis of BPD in a plaintiff provides the defense opportunities to support legal arguments unique to sexual harassment litigation. One common defense strategy is to argue that PTSD claimed as damages in a sexual harassment case is likely to have been caused by a history of previous sexual abuse or victimization. These legal arguments take advantage of research that has found consistent and statistically significant associations between a history of childhood sexual abuse and diagnoses of BPD and PTSD (Ogata et al. 1990; Zanarini 1997; Zanarini 2000; Horwitz et al. 2001; Golier et al. 2003; Bandelow et al. 2005).

Features of BPD, such as dysfunctional coping, emotional reactivity, dysfunctional patterns of interpersonal behaviors, and perceptual distortions of self and others, are relevant to legal elements of a sexual harassment claim. By definition, sexual harassment must be "unwelcome" to be illegal. The legal standard applied to the question of whether behavior rises to an actionable level includes whether a "reasonable person" would have found the behavior offensive or distressing. Employers are not necessarily liable if plaintiffs demonstrate "hypersensitivity" to the comments or behaviors of others.

Defense attorneys may argue that prior sexual abuse, implied even if not proven by a diagnosis of BPD, renders abused individuals "hypersensitive"—that is, more likely to inappropriately interpret and label innocuous workplace behavior as sexual harassment. Defense attorneys may use a BPD diagnosis to claim that the plaintiff's perception of the alleged harassment is not credible due to cognitive distortion caused by BPD. Features of BPD may be invoked to argue that the plaintiff was an active participant in the events that she is now disavowing (playing on the gender stereotype of "a woman scorned"), thus undermining claims that the alleged harassment was unwelcome.

Psychiatric evaluation in sexual harassment cases should include consideration of behavioral patterns or cognitive processes that might affect interpersonal relationships or cause perceptual distortion. Determination of an individual's tendency to invite, misinterpret, distort, or overreact to the behaviors of others is a critical part of a sexual harassment assessment, whether due to BPD or any other psychological process, such as an underlying psychosis or paranoid thought disorder.

However, defense examiners often inappropriately assign a diagnosis of a personality disorder based on a plaintiff's current presentation. Women who have experienced sexual harassment, made a formal complaint, perhaps experienced retaliation, and experienced the stress of litigation can appear histrionic, angry, defensive, or reactive on evaluation, even in the absence of pre-existing psychiatric disorders (Lenhart 1996). This presentation may be exacerbated by the stress of undergoing a psychiatric evaluation, particularly by clinicians retained by the defendants, leading forensic examiners to assign a diagnosis of BPD in the absence of evidence that such a diagnosis was present prior to their examinations.

These psychiatrists may cite a narrow and outdated body of forensic literature, unsupported by research, asserting that individuals who have suffered childhood sexual abuse are both more likely to report sexual harassment and to claim the harassment has caused PTSD when compared to those without abuse histories (Feldman-Schorrig 1994; McDonald and Lees-Haley 1995; Feldman-Schorrig 1996). Moreover, methodologically sound research studies have shed considerable doubt on the assumption that claims of PTSD should be dismissed if evidence of prior trauma or prior psychological dysfunction is produced (Fitzgerald et al. 1999a; Stockdale et al. 2002; Stockdale et al. 2009).

Forensic evaluators should be cautious about making a personality disorder diagnosis based solely on the events in the case but in the absence of an adequate supporting longitudinal history. A diagnosis of a personality disorder

should be based on lifelong, pervasive, and inflexible patterns of dysfunction and maladaptive coping. Individuals with personality disorders typically have histories of chaotic lives and problematic interpersonal relationships across all spheres of functioning. Evidence of such patterns and dysfunction requires review of previous employment history and records, prior and current interpersonal functioning in other areas of life, and even prior litigation history. Psychological testing can also provide valuable data in making this diagnostic determination.

SUGGESTED PRACTICES IN SEXUAL HARASSMENT AND GENDER DISCRIMINATION EVALUATIONS

1. *Maintain neutrality.* Psychiatric evaluators should avoid making assumptions about the facts of a case that can prejudice their opinions. The use of psychological testing with multiple validated measures as well as structured diagnostic interviews may help provide objective data to support opinions in sexual harassment evaluations (Lawson et al. 2013), but testing may not be indicated in all cases.
2. *Avoid the dual role of treating clinician and expert witness.* Sexual harassment cases present difficulties in occupying both roles beyond those usually associated with "wearing two hats" (Strasburger et al. 1997). Trying to occupy both roles can harm both the therapeutic relationship and the patient's litigation.
3. *Review all available documents.* This includes medical, legal, psychiatric, pharmacy, EEOC, investigative, and employment records. In cases where civil charges are filed in conjunction with or after the filing of criminal charges such as assault, battery, or rape, police records may be available.
4. *Conduct a complete assessment.* Clinicians should conduct a clinical interview of appropriate length, record review, and when possible, collateral interviews with third parties. In some cases, clinicians may need to conduct a site visit. Clinicians should also be aware that the evaluee's mental health history may not have begun with the alleged harassment. Obtain as extensive a history as possible, including review of past and current sources of trauma, and review of the claimant's litigation history, employment history, and history of interpersonal relationships.
5. *Decline to provide opinions outside areas of expertise or that are the purview of the court.* Attorneys will frequently exert pressure on experts to provide opinions beyond the boundaries of training and experience, and sometimes past the boundaries of the field of psychiatry. Psychiatrists should avoid providing opinions in areas in which they lack expertise, in which a scientific basis for opinions is lacking, or which are essentially legal arguments, not psychiatric conditions, such as "welcomeness," "reasonableness," and "credibility."
6. *Assess each case on its own merits.* Relevant research findings can be used to support opinions, but research findings cannot provide data about individual cases. Forensic clinicians should base their opinions on the case's specific facts and data, and should be prepared to defend those opinions on that same basis. Besides representing competent practice, familiarity with the specific facts of the case will help overcome legal arguments that an expert's testimony is not legally relevant (Gold 2004).

SUMMARY

A general definition of sexual harassment and gender discrimination does not exist. The complex nature of human relationships and behavior defies the development of social or legal formulas defining when conduct is offensive, and when offensive conduct is illegal. Fortunately, forensic psychiatrists are not tasked with providing universal definitions or legal determinations in sexual harassment and gender discrimination cases.

Nevertheless, forensic psychiatrists can offer expert opinions and testimony regarding the aspects of sexual harassment and gender discrimination that fall within psychiatric training and expertise. Credible opinions, based on professional expertise, guided by forensic and clinical psychiatric ethics and methodology, and informed by relevant social science are of value to all parties in sexual harassment cases. Forensic psychiatric expert testimony based on these fundamental practices and on relevant research can assist the court in clarifying the complex issues that arise in sexual harassment and gender discrimination litigation.

SUMMARY KEY POINTS

- Illegal sexual harassment in the workplace is a subset of gender-based workplace discrimination, defined by federal, state, and case law.
- The EEOC has defined two types of sexual harassment: *quid pro quo* and hostile work environment.
- Psychiatric evaluations in sexual harassment or gender discrimination should include characteristics of the harassment, premorbid functioning of the plaintiff, prior work history, the effects of retaliation, the effects of litigation, as well as other factors.
- Sexual harassment is adversely related to job-related, psychological, and physical outcomes, but the severity of the harassment is usually the

primary predictor of psychological outcome. More severe outcomes to less severe harassing behaviors raise issues of pre-existing psychological vulnerability.
- Personality disorder diagnoses should not be made in the absence of a longitudinal history consistent with these disorders.
- Psychiatric evaluators in sexual harassment litigation should maintain neutrality, avoid dual agency, review all documents, and conduct a complete assessment.

Civil competencies

J. RICHARD CICCONE AND JOSHUA C.W. JONES

INTRODUCTION

Western civil tradition assumes that adults have the capacity to make their own decisions. In specific instances courts are asked to intercede and abridge these rights. The courts are entrusted to protect a person from his or her own inability to make rational decisions, or to protect others from the same. Forensic psychiatrists, in turn, are often asked to provide an evaluation and opinion on whether and how mental illness impacts a person's ability to make decisions.

Because the right to make one's own decisions is held as fundamental, significant allowance is made for error, mistakes, and poor judgment. A person need not make excellent decisions to be considered competent; the threshold is usually quite low, just high enough to be considered rational. However, this threshold is a sliding scale with the definition of *rational* viewed in context of the decision's circumstance and potential for harm. Ultimately, a court makes the final decision as to whether a person is competent. The law is purposefully written in broad strokes that provide guidance, but not prescription, to the judicial fact-finder because laws cannot be written specifically enough to cover all situations.

DEFINITION AND COMPONENTS OF CIVIL COMPETENCY

In clinical settings, the evaluation of a person's ability to make decisions is called a "capacity evaluation." Forensic psychiatrists may provide an opinion on competency (i.e., capacity), but only the court can make a competency determination. Therefore, the forensic psychiatrist should be familiar with the legal standard for the competence being evaluated in the jurisdiction where the issue is to be adjudicated.

The essential abilities necessary to make a reasoned decision are surprisingly universal and applicable to many situations. In order to have the capacity to make a decision, a person must be able to understand the nature and consequences of the decisions to be made, rationally manipulate information that might influence that decision, and be able to communicate a choice. This basic decision-making analysis can be applied repeatedly, with differing specific parameters based on the competency being examined. Competence is decision specific; an individual may be competent in one area but not competent in another. Therefore, although the general steps necessary for the determination of competence provide a useful template, the specific questions to be answered are contextual. In this chapter we provide a general guide for conducting a forensic evaluation of civil competence and several examples that are illustrative of general and specific principles.

CONDUCTING THE CIVIL COMPETENCY EVALUATION

Before undertaking the evaluation, the forensic psychiatrist should first understand the context of the referral and clarify the question being asked. Frequently, the referral source (courts, attorneys, insurance companies, other physicians, etc.) may not have completely formulated a cogent question, and the forensic psychiatrist may help them frame the inquiry so that there can be an answer and a useful outcome. The evaluating psychiatrist should know who is seeking the evaluation, for what purpose, and how the findings will be used.

The role of the forensic psychiatrist is to determine whether the person in question suffers from a mental disorder. If there is no mental illness, the forensic psychiatrist's job may be finished after telling the court of this finding. If the individual does have a mental disorder, the task next becomes to determine whether or not the presence of the disorder impacts the individual's competency in question, and if so, to what extent. The presence of a mental disorder does not necessarily render a person incompetent. This concept is frequently foreign to referral sources, and the forensic psychiatrist will need to address this distinction in his or her report.

Generally, the forensic psychiatric evaluation is composed of three complementary components: (1) the psychiatric examination, (2) record review, and, when indicated,

(3) psychological testing. The psychiatric examination is the clinical diagnostic interview and observations as distinguished from the forensic psychiatric evaluation, which includes the integration of record review and testing. When a forensic psychiatrist is asked to render an opinion without one or more of these components, he or she should explain in the report how these conditions affect the outcome.

EXAMINATION

When performing a forensic psychiatric evaluation, the psychiatrist should endeavor to conduct a personal psychiatric examination whenever possible, although in some instances (e.g., contested wills, psychological autopsy, unwilling subject) it may not be possible. Informed consent should be obtained, including an explanation of the examiner's role and by which party he has been retained, how the examination will be used, and who may have access to the information gathered. The individual should be informed that the usual doctor–patient relationship is not created by the examination. The examinee retains the right to refuse to participate in the evaluation, and that refusal may be disclosed to the referring party.

The forensic psychiatrist may decide to record the examination (American Academy of Psychiatry and the Law 1999), and we support recording when feasible. The psychiatrist should inform the retaining party of the intent to record, allowing the party to make appropriate disclosures. Audio and/or video recording can be reviewed by others, can help refresh the memory of the examining psychiatrist, and can be helpful during trial. If consent for the examination is obtained prior to recording, we recommend that the evaluee re-consent during the recording.

The amount of time spent in evaluation is not the most important variable in the examination; sometimes the answer is obvious after a few minutes and sometimes the answer is obtuse, requiring multiple examinations. Time spent in the examination needs to be judiciously tailored to account for not only the intricacies of the examinee's clinical presentation but also the complexity of the competency question at hand. Accounting for outlying amounts of evaluation time in the forensic report will enhance the credibility of the final opinion.

Malingering is a universal concern in forensic psychiatry. In the criminal setting, the malingering subject is more likely to feign signs or symptoms of mental illness in order to escape or postpone consequences of his or her criminal charges. In the civil setting the impaired individual may attempt to disguise or minimize symptoms in order to retain rights that he or she fear may be limited. This should be investigated in the examination and addressed in the report.

RECORD REVIEW

Reviewing all pertinent, available records is an essential part of the forensic psychiatric evaluation. This allows the psychiatrist to corroborate or question the examinee's narrative and can give a more complete overview of the examinee's case. The psychiatrist should ask, usually in writing, for the referring party to send any and all relevant records relating to the case, and should specify any essential documents to avoid confusion. Acquisition and review of psychiatric and nonpsychiatric medical records is of utmost importance in establishing diagnoses. Legal documents pertaining to the matter at hand (e.g., wills, contracts) are also essential to review. Documents that can help a psychiatrist reconstruct the thought processes of the examinee, such as letters, journals, or social media posts, can give a contemporaneous window into an examinee's thought processes.

We recommend striving to review available records prior to the psychiatric examination to afford the psychiatrist the opportunity to ask the examinee to comment on inconsistencies, oddities, or other relevant points of interest found in the records. This can also help the psychiatrist structure the examination in more efficient and meaningful ways. If the complete record is not available before the examination, the forensic psychiatrist can inform the retaining party that additional examination time may be needed if the record review reveals previously unknown points of interest. While reviewing records, note taking is helpful in organizing voluminous amounts of information. Because such notes are discoverable and can be a source for cross-examination, they should be professional, factual, and without editorial commentary. This caveat holds true for notes taken during the psychiatric examination as well.

TESTING

The use of forensic assessment instruments may be a valuable adjunct to the forensic psychiatric examination and record review (Grisso 2003). Many instruments that have been created over the past 20 years have varying applicability to different circumstances and test populations, and vary widely in their validity and reliability. The evaluating forensic psychiatrist must select tests according to their reliability and appropriateness for each examinee. Often the use of psychological testing requires consultation with a psychologist.

Some tests, (e.g., Minnesota Multiphasic Personality Inventory-2 [MMPI-2] [Butcher 2011], Personality Assessment Inventory [PAI] [Morey 2015], and Millon Clinical Multiaxial Inventory [MCMI] [Choca and Grossman 2015]) provide insight into the individual's personality and psychopathology, identify critical risk items to be considered, and give an indication of how forthcoming the test taker has been (fake good/fake bad profiles). Although these instruments do not provide a functional evaluation, they can assist the forensic examiner with identifying the presence of a significant psychiatric disorder.

Frequently, civil competency evaluations question a person's cognitive abilities. Several screening instruments for cognitive dysfunction (e.g., Folstein Mini-Mental State Examination [MMSE] [Folstein et al. 1975], Montreal

Cognitive Assessment [MoCA] [Nasreddine et al 2005], Saint Louis University Mental Status [SLUMS] [Tariq et al. 2006], and Cognistat [Kiernan et al. 1987]) are widely used in the clinical realm and can be used to help the forensic psychiatrist determine if a full neuropsychological evaluation is indicated. Further neuropsychological testing can identify specific areas of impairment that may diminish an individual's ability to make a decision in the civil arena.

Other forensic assessment instruments gather data regarding the individual's functional capacity. These tests include the Adult Functional Adaptive Behavior Scale and the Multidimensional Functional Assessment Questionnaire (Grisso 2003). Some of these instruments may require the input of others (family, caretakers, etc.); therefore, the reliability of these instruments may be influenced by the accuracy of information provided by third parties. Forensic psychiatrists must be confident that the instruments utilized are appropriate and will withstand scrutiny. If a consultant is used, the psychiatrist should discuss with the consultant, prior to test commencement, which tests would be most appropriate to administer. Finally, forensic evaluators should understand their limitations of expertise. Some cases may be complex and require collaboration with other disciplines, such as neurology or psychology, or other psychiatrists with subspecialty expertise, such as child and adolescent psychiatry.

Some unusual cases may require the assembly of a multidisciplinary team.

WRITING THE CIVIL COMPETENCY REPORT

As experts, the forensic psychiatrists' task is to provide a clear explanation of the evaluation process, what was discovered, and the rationale behind the opinion regarding the individual's capacity to make the decision in question. The report is one way that the forensic psychiatrist communicates with the court and others in the legal system. The quality of report influences the weight given to the opinion. The report should include applicable psychiatric diagnoses, the opinion regarding the evaluee's competence, and the reasoning that links the two together. The written explanation of the reasoning is vital, adds credibility to the conclusions, and helps the fact-finder understand that the psychiatrist used a rational method for decision making.

Some have suggested that the forensic psychiatrist should not give an opinion on the ultimate question of competency, but simply lay the facts in front of the fact-finder (Bazelon 1989). We disagree, and remind the reader that the fact-finder is making the final decision regardless of the forensic psychiatrist's opinion, but that the forensic psychiatrist has the unique skill set to assist the court in linking the facts of the case with psychiatric knowledge to arrive at a reasoned opinion (Ciccone 1987).

The forensic psychiatrist should not write a report unless requested to do so by the retaining party. Once a report is requested, we recommend discussing the draft with the attorney verbally and never releasing a copy of a draft. Attorney suggestions on factual and grammatical errors and omissions can be considered while striving to maintain objectivity and fidelity to one's own psychiatric opinion.

SPECIFIC COMPETENCY EVALUATIONS

Guardianship

In most jurisdictions, there is a presumption of competency when adults enter into contractual arrangements or make decisions as they live their lives. Under the concept of *parens patriae*, the state has the authority to protect incompetent individuals and to preserve their property. A guardian is a person to whom the courts have given the power of managing the property and the personal interests of another person. These responsibilities may include the duty to make decisions regarding the physical needs of the person who, for defect of age, understanding, or self-control, is considered incapable of administering his or her own affairs. A guardian has a fiduciary responsibility to manage the affairs of the ward and may be held accountable for errors in transacting business affairs on the ward's behalf. A guardian does not have title to property that remains with the ward.

There are different types of guardians. A *testamentary guardian* is appointed for a child by a will and has responsibility for both the child and the child's estate until the child reaches the age of maturity. A *guardian ad litem* is appointed by the court to protect the interests of a minor, an incompetent, or a proposed conservatee in litigation. A *special guardian*, also known as a limited guardian or a conservator, has powers limited to managing a ward's financial affairs. A *general guardian* has the additional obligation to provide for the ward's personal needs including housing, clothing, food, health care, recreation, and education. These general definitions may have different names depending upon jurisdiction.

HISTORY

The tradition of protecting the property of an incompetent individual, integral to English Common Law, made its way to colonial America. In colonial times, it was expected that the immediate family would care for the incompetent individual. If necessary, the colony had the ability to act to protect the interest of the incompetent (Johns 1999). These efforts represent an attempt to preserve the estate of the incompetent so that those who have rightful claims against the estate, as well as those who could be expected to be supported by it, would be protected from having the estate dissipated by the incompetent.

An Associated Press report released in 1987, "Guardians of the Elderly: An Ailing System," found that the guardianship system in the United States had many weaknesses (Bayles 1987). The report stated that courts "routinely take the word of guardians and attorneys without independent checking or full hearings." The American Bar Association has responded and recommended more effective monitoring

of the guardianship system, standardized training for judges and guardians, and robust periodic court review (Hurme and Emily 2001).

In 2010, the Government Accountability Office (GAO) identified hundreds of allegations of physical abuse, neglect, and financial exploitation by guardians, and found that potential guardians were not adequately screened or monitored, and courts and federal agencies did not communicate effectively about abusive guardians. Consequently, the forensic psychiatrist should understand the weaknesses and vulnerabilities of the guardianship system into which his or her evaluation might place an individual.

GENERAL GUARDIAN

A general guardianship, in some jurisdictions called a "committee of the person," involves a finding of global incompetence and is a drastic measure with far-reaching consequences. It is relatively difficult to accomplish because the courts have been reluctant to take an individual's right to manage his or her own affairs. The burden of proof is on the person bringing the petition. Appointment of a guardian requires evidence that the ward suffers a substantial impairment of his or her ability to manage property or has become unable to provide for himself or herself or dependents due to a specified disability. A showing that a person suffers from a mental disorder alone is insufficient. There must be clear and convincing proof of substantial impairment in the proposed ward's ability to manage his or her affairs (*In re Bailey* 1974). Expert testimony is not required but is usually employed. The physician—usually a psychiatrist—who undertakes a competency evaluation is not assessing competence in the abstract, but rather with respect to the ability to make specific informed decisions. The specific criteria used in the creation of a guardianship vary from jurisdiction to jurisdiction.

LIMITED GUARDIAN

In recent decades there has been a movement toward the establishment of specific guardianships for specific purposes (Brakel et al. 1985). In some jurisdictions the law provides for the creation of a *conservatorship* to ensure the financial well-being of an individual. A conservatorship does not require that the person be found globally incompetent, just that the person cannot manage his or her affairs as the result of physical and/or mental dysfunction.

Due process rights require that notice of the petition for conservatorship be served on the proposed conservatee, and the conservatee may be present and a guardian ad litem may be appointed to represent the proposed conservatee's interests. If a conservator is appointed, the court sets forth a specific plan as to the duration of the appointment and the frequency of reports to the court.

A family member is usually appointed as conservator, but a nonfamily member may be appointed, especially when there are family disagreements. When there is no family member available, the court may appoint a nonprofit corporation as conservator. It is possible for a Department of Social Services to act as conservator, even if the conservatee does not receive public assistance. A conservator looks after the ward's assets and supplies his or her needs but does not have legal decision-making capacity regarding consent to treatment; that usually requires the creation of a general guardianship.

TERMINATION OF GUARDIANSHIP

Wards who think that they have recovered the ability to manage their affairs can apply to have competence restored. Some jurisdictions call for periodic review of incompetence, and other jurisdictions have provisions for automatic restorations of competence. If there is a finding of restoration of competence, the individual regains his or her right to make personal and financial decisions, and the guardian is relieved. The termination of a guardianship also requires informing relevant individuals about the hearing. There is variation among jurisdictions regarding who should be notified and who must be present at the hearing.

CONDUCTING THE FORENSIC PSYCHIATRIC EVALUATION FOR GUARDIANSHIP

The psychiatric expert evaluating an individual for guardianship should be mindful of the potential abuses of guardianship. Information about who raised the issue of the individual's need for a guardian, why it is being sought, and the effects of a general or limited guardianship is important for a careful evaluation.

In addition to the general guidelines for record review stated above, recent bank statements and bills may provide information about the evaluee's functional financial ability. The evaluee also needs to have a reasonable understanding of his or her sources and amount of income, as well as expenses. An assessment of adaptive functioning is also important. Can the evaluee safely navigate through his or her day, not only providing for shelter and sustenance, but also for personal safety and well-being? Given the evaluee's possible wish to portray a more functional status than is reality, corroborating accounts or observations from family, friends, and other close associates can provide information, as can a visit to the person's home, especially observing the person in his or her home (Melton et al. 2007). Conversely, corroborating information can sometimes cast doubt on the petitioner's assertion that the evaluee needs guardianship, especially when potential financial gains are in play.

The psychiatric examiner should consider whether treatment or the introduction of social support services will allow a person to remain independent. In this way, the forensic psychiatrist provides the court with clinically relevant and legally useful information about an individual's ability to make and communicate decisions regarding one's self and property in varying contexts.

Testamentary capacity

The law presumes that an individual has testamentary capacity—that is, he or she is of sound mind when executing

or altering a will. Testamentary capacity requires that a testator or testatrix has the ability to know and rationally understand (1) that he or she is making a will; (2) the natural objects of his or her bounty and claims upon them; and (3) the general nature and extent of his or her property (Garner 1999). In some jurisdictions, the testator must have a rational plan for the distributions of his or her property after death (Regan and Gordon 1997; Gutheil 2007).

HISTORY

In feudal times, fixed rules governed the inheritance of real property. Even when primogeniture, which gave the eldest son the right to inherit his father's estate, was the rule, there were significant exceptions where local customs prevailed. For example, in Kent, England, there was gavelkind tenure, which gave equal shares to sons (Friedman 2005). In 1572, the English Statute of Wills provided everyone with the right to make a will to dispose of real (immovable) and personal (movable) property. Over time the law was amended to exclude "idiots" or persons with "insane memory" (Brakel et al. 1985).

Colonial America used a variety of approaches to wills. New England colonies rejected primogeniture, except for Rhode Island, although Massachusetts and Pennsylvania gave a double share to the oldest son. Southern colonies used primogeniture until revolutionary times (Friedman 2005). American probate laws followed the English Statute of Frauds of 1677, which called for a written, witnessed will for real estate. By the time the nineteenth century ended, an increasing number of individuals left wills crafted by an attorney (Natale 1989).

WILL CONTEST

Less than 3% of wills are contested, and of those that are contested only 15% are successfully overturned (Slovenko 1973). There are a number of conditions that can invalidate a will, one of these being the effects of a person's mental condition at the time of the execution or alteration of the will. In a will contest there is the presumption of testamentary capacity, and the burden of proof rests with the party alleging incompetence. In most jurisdictions the "clear and convincing" standard must be met before the will is invalidated. A testator's suicide does not automatically invalidate a will. A previous adjudication of incompetency—such as the appointment of a guardian—also does not prevent establishing a valid will (Redmond 1987); however, the burden of proof is shifted (Bromberg 1980), and the proponent of the will must establish by clear and convincing evidence that the will was made during a "lucid interval" (*In re Will of Coe* 1900).

The concept of a lucid interval is based on the notion that an individual with a major mental disorder may have periodic remission of symptoms and during such an interval may have the minimal abilities to fulfill the legal criteria for testamentary capacity. Lucid intervals may be found in individuals who abuse alcohol or drugs, unless the substance use has led to some chronic, significant mental deterioration. At times this doctrine has been applied to the individual who is allegedly lucid for only a few minutes. However, "a few minutes" are usually insufficient for the individual to assess and comprehend the factors involved in the distribution of assets.

RETROSPECTIVE DETERMINATION

The evaluation of testamentary capacity frequently occurs after the testator's death. This precludes personal examination, an important source of information, and calls for a thorough examination of other sources. Essentially, retrospective evaluation is a psychological autopsy and can result in a useful description of the testator's mental status and functional ability at the time the will was created or altered. When undertaking a retrospective determination, the psychiatrist must rely on information from collaterals (friends, business partners, relatives, neighbors, hospital and nursing home staff, etc.) and a review of relevant records (school, military, work, medical, psychiatric treatment, etc.). It is also helpful to review letters and notes written by the deceased, especially around the time of the creation or alteration of the will. A visit to the residence or nursing home of the deceased may be useful (Perr 1981). An independent accounting of the nature and value of the testator's estate should be available. Despite the evaluator's best efforts, the unavailability of the testator may result in insufficient data to arrive at an opinion. The forensic psychiatrist must be confident in his or her diligence and be able to communicate this lack of a finding to the retaining party.

INSANE DELUSION

A delusional testator may appear well to the psychiatrically untrained. The court is interested in what is legally called an insane delusion; that is, a mistaken belief for which there is "no basis in reason, cannot be dispelled by reason, and can be accounted for only as the product of mental disorder" (Am. Jur. 1975). As with other instances of civil competence, the mere existence of a delusion does not invalidate a will, and most jurisdictions require proof that the delusional beliefs affected the creation or alteration of the will. Insane delusions often involve demented individuals who believe their spouse is having an affair.

The *Estate of Coffin* is frequently cited and involves the issue of insane delusion (*In re Estate of Coffin* 1968). Coffin married a woman who claimed that he had fathered her child, although she had been with other men. Shortly thereafter, they divorced and he had nothing to do with this child. Forty-one years later, Coffin met this child for the first time and, based on resemblance, decided that this was indeed his son. Before he could formally change his will, Coffin, Sr., died. His son went to court to challenge the validity of the will that had been written at a time when Coffin, Sr., did not believe he had a son. The lower court vacated the will because Coffin, Sr., wrote its provisions while under an insane delusion that this woman's child was not his son. The appellate court dismissed this argument and found Coffin, Sr., did not have an insane delusion when

he wrote his will. There was sufficient information for him to believe that this woman's child was not his, and although he was mistaken, he was not insanely deluded. The court held that the petitioner has the burden to prove, by clear and convincing evidence, that there were not facts to support the testator's belief. The judgment invalidating the will was reversed.

In another case, Estoll left the bulk of her estate to her only child, a daughter. The codicil, executed 4 years later, left the bulk of her estate to her sister without mention of her daughter (*In re Estoll* 1968). The daughter opposed probate of the will and presented evidence that her mother had an insane delusion that "the person who would normally be the principal or only object of the testatrix's concern and bounty" was trying to poison her, as the decedent had told many people. She also would not accept pills or water from her daughter but accepted them from her sister. The codicil was set aside on the basis of the impact of this insane delusion.

UNDUE INFLUENCE

Undue influence involves manipulation or deception in engaging the affections of the testator, significantly impairing his or her ability to freely decide on the distribution of his or her property. By its nature, undue influence is often the result of concealed actions and may be difficult to determine. A noble purpose does not justify or legitimize undue influence, such as a physician convincing an elderly patient to leave the bulk of her estate to his research institute. Undue influence must constitute more than friendship or insincere praise. There must be evidence of coercion, compulsion, or restraint that led to a will that does not reflect the true desires of the testator. Some grounds for undue influence include harassment, threat of abandonment, and disaffecting lies about another potential heir (Perr 1981). The burden of proof is on the fiduciary heir to prove that no undue influence was exercised. A fiduciary relationship is one where an individual relies on and trusts another (e.g., attorney–client, doctor–patient, or guardian–ward). However, if the heir is not a fiduciary, the burden of proof falls to the party challenging the will.

The forensic psychiatrist can be asked to examine for undue influence after the testator is deceased, and should consider undue influence in testamentary capacity examinations requested around the time a testator is making or altering a will. The following circumstances provide reasons to consider the possibility of undue influence (Redmond 1987):

1. The psychiatrist is assured by the party requesting the examination that a competency statement is routine due to the testator's age.
2. The appointment is made by someone other than the testator or his or her attorney.
3. The testator is brought to the appointment by someone who answers most of the questions and is reluctant to allow the testator to be interviewed alone.
4. Specifics about the will are not given or the testator seems unclear about specific items in the will.
5. There is reluctance to give information about potential heirs and their relationship to the testator.

The psychiatrist must consider cognitive functioning, physical condition, and signs and symptoms of mental disorders that may reduce the testator's ability to resist undue influence. These same ailments may be so severe that the individual may also lack testamentary capacity.

When psychiatrists are not be able to arrive at an opinion as to whether or not there was undue influence, they may nonetheless opine if the individual's character structure—either alone or in combination with a physical or mental condition—made them particularly susceptible to the influence of others. The social environment of the testator may create the opportunity for undue influence on the cognitively impaired person by a cohabiting family member, a "helpful" neighbor, a "suitor," or professionals. A variety of social circumstances increase the possibility of undue influence: isolation from previously trusted family and friends, family conflict, or significant dependence on a caregiver (Peisah et al. 2009).

CONDUCTING AN EVALUATION FOR TESTAMENTARY CAPACITY

When the testator is available for examination, such as in the case of an anticipated challenge to the will, the customary psychiatric examination of an adult is appropriate (American Psychiatric Association 2006). If attorneys are to observe the interview, a one-way mirror allows for observation without undue intrusion; otherwise, the attorneys may be seated behind the examinee to minimize contact. It is useful to record this examination (Spar and Garb 1992), which may obviate the need for the attorneys' presence and provide compelling information for the court to consider.

If cognitive impairments are noted and are difficult to fully delineate on clinical examination, neuropsychological testing should be considered. The psychiatrist should be alert to psychological motivations that could include, but are by no means limited to, hostility toward heirs, fear, or "secrets" that the testator holds dear. The psychological and cognitive impact of nonpsychiatric medical problems cannot be ignored; disabilities secondary to physical problems must be factored into the decision-making process. Even if the presence of a significant mental disorder is obvious on examination, the evaluator must determine whether and how the signs and symptoms influence the decision-making process required to execute a valid will. For example, the testator with a mild dementia may have difficulty recalling new information, but may nonetheless know his children, the approximate size of his estate, and that he wishes to reward the child with whom he is living with a larger share of the inheritance.

The evaluator should ascertain whether the testator understands the purpose of a will. Testators should be

asked to describe their property and estimate its value. They should also be asked to describe the division of their estate, their heirs, and the reasons underlying their decision to include or exclude potential heirs. This line of questioning is also an opportunity to assess for evidence of undue influence. Testamentary capacity requires comprehension of the overall size and components of one's estate. Although precise knowledge of the value of the estate is not required, the individual should have a reasonable approximation of its overall worth. An individual must also know the natural objects of one's bounty; generally, these are blood relatives, though at times they may include close friends, and occasionally a "faithful servant." The testator's denial that he has children based on the symptoms of a mental disorder may invalidate a will. However, ignorance of the existence of blood relatives (i.e., not due to delusion) does not constitute incompetency. The inability to read or write also would not, by itself, invalidate a will.

Competence to contract

Competence to contract, or contractual capacity, refers to an individual's capacity to enter into agreements. Society places a great deal of importance on the sanctity of the contract. Pettit (1999), in reviewing the evolution of contractual rights and the mentally ill, noted, "The most striking change is that the mentally disabled are now allowed to contract at all."

HISTORY

In a 1963 seminal case, *Faber v. Suite Style Manufacturing Corporation*, Faber contracted for land against the advice of his attorney. Faber planned to use the property to build a resort. Expert witnesses agreed that Faber was in the manic phase of his bipolar disorder at the time he entered into the contract. The court found Faber incompetent to enter into the contract because he acted "under the compulsion of a mental disease or disorder but for which the contract could not have been made."

In *Ortolere v. Teachers' Retirement Board* (1969), the court expanded the scope of mental incompetency that may void a contractual agreement. Ortolere, while under psychiatric care, changed her retirement option to a maximum allowance that extinguished all interests upon her death. Her husband sued, claiming she was not mentally competent to enter into this agreement. The court found that Mrs. Ortolere suffered from an involutional psychosis, melancholia type (major depressive disorder, severe with psychotic features) on the date she entered into the contract. Determining that the cognitive rules for incompetence were too restrictive, the court expanded the grounds of incompetence to include affectively driven behaviors resulting from a psychosis. The court found the contract void because she was laboring under a mental defect that prohibited her from acting in a reasonable manner, and the Board of Education knew of the impairment because Ortolere's mental illness led to her leave of absence.

CONTRACTUAL CAPACITY IN GUARDIANSHIP

Some have argued individuals who have a guardian, as a matter of law, have no ability to enter into a contract (Meiklejohn 1988). Those holding this view assert that the ward has been found incompetent, and in order for the guardian to protect the ward's estate, the guardian has to have control over it. The opposing view argues that the order establishing a guardianship creates a rebuttable presumption of incapacity to enter into a contract. They further argue that the state has an interest in upholding contracts, and those dealing with the ward may not have had constructive notice of the guardianship and may have acted in good faith. Most jurisdictions take a middle position, allowing for an individual to be found incompetent to enter into a contract but requiring the person requesting that the contract be voided to carry the burden of proof. To lack contractual capacity, the court must be convinced that the individual had a significant mental disability that impaired his or her capacity to understand the character of the transaction and act in a reasonable manner. In some jurisdictions, it must be shown that the other party knew of the incompetency or acted in bad faith. At times, the "fairness" of the contract will determine if it will be upheld by the court.

CONDUCTING THE FORENSIC PSYCHIATRIC EVALUATION FOR CAPACITY TO CONTRACT

As with the evaluations of other civil competence, the context of the request is important. The determination of the presence of a mental disorder and the resulting impairments is essential to determining an individual's capacity to enter into a contract. Although much of the case law and academic discourse in the literature focuses on commercial contracts, a contract is essentially any lawful agreement between two or more parties, and could include marriages and adoptions.

Capacity may vary over time depending on the nature, severity, and periodicity of a person's disorder. Additionally, in more complex contracts, a higher standard of capacity is required. Prior to the psychiatric examination, the psychiatrist should request a detailed explanation of the terms of the contract. During the psychiatric examination, the evaluee should be asked to explain the terms and his or her reasoning for deciding to enter into the contract.

SUMMARY KEY POINTS

- The forensic psychiatric evaluation of civil competencies is composed of three complementary components: the psychiatric examination, record review, and, when indicated, standardized testing.
- Appointment of a guardian requires evidence that the ward suffers a substantial impairment of his or her ability to manage property or has

become unable to provide for himself or herself or dependents due to a specified disability.
- Testamentary capacity requires that a testator or testatrix has the ability to know and rationally understand that he or she is making a will, the natural objects of their bounty and claims upon them, and the general nature and extent of his or her property.
- Undue influence involves manipulation in engaging the affections of the testator, which impairs the testator's ability to freely decide on the distribution of his or her property.
- The complexity of a contract is directly related to the capacity required to competently enter into it.

Death, dying, and the law

M. CARMELA EPRIGHT AND RICHARD L. FRIERSON

INTRODUCTION

The "right-to-die" movement in the United States stems from the 1960s, an era that brought tremendous advances in medical technology such as the widespread use of mechanical ventilation, renal dialysis, and artificial nutrition. These interventions made it possible to preserve lives that would have been lost mere decades earlier, but they also had the capacity to prolong the dying process, often beyond limits found acceptable by the patients whose lives they were intended to preserve. Consequently, phrases such as "quality of life" and "death with dignity" have taken on political, social, and personal significance in the public sphere (Beauchamps and Childress 2009). Patients and families have since sought new laws, health-care policies, and rights, including the right to withdraw treatment, assign surrogate decision makers, and receive increased access to palliation, analgesics, and sedation. In some jurisdictions, patients and their caregivers have successfully argued for laws that promote a patient's choice to hasten death through physician-assisted suicide.

These overtures have been met with significant resistance. Religious groups argue that life itself must be preserved regardless of a patient's or surrogate's desires (Hains and Hulbert-Williams 2013). Human rights activists fear the potential abuse of euthanasia on members of vulnerable groups such as the indigent and the disabled (Van Norman 2014). Many medical providers prioritize cure and treatment over a strong conception of individual autonomy (Boudreau and Somerville 2013). Moreover, the drive toward patient-directed treatment at the end of life has been seen as a challenge to the traditional authority of physicians who are thought by some to be more qualified to make end-of-life decisions than persons without medical training (Filene 1998; Boudreau and Somerville 2013).

DONALD "DAX" COWART: TREATMENT WITHDRAWAL

The early 1970s brought several highly publicized cases that illustrate the conflict between preservation of life and the patient's right to refuse treatment. One of these high-profile cases involved 25-year-old Donald "Dax" Cowart who was critically injured in a 1973 explosion that killed his father. Cowart sustained second- and third-degree burns over 65% of his body. From the very beginning he clearly expressed a desire not to be treated for his injuries. His health-care providers continued to treat him, asserting that the pain associated with his treatment made him incompetent to make decisions about his care. Cowart's mother signed consent forms for any procedure deemed necessary by the health-care professionals (Kliever 1989). Because the accident rendered Cowart completely blind, partially deaf, fingerless, and unable to walk without assistance, he was not able to leave the hospital on his own accord and was thus forced to undergo whatever treatments his health-care providers recommended. During his hospitalization multiple psychiatrists concurred that Cowart was competent to make medical decisions. Cowart argued that his treatment should have been terminated when—as a competent adult—he asked to leave the hospital and return home to die from his injuries (Cowart and Burt 1998).

After Cowart was released from the hospital he became a successful attorney and advocate for the "right-to-die" movement. His case has since been considered one of the best examples of the importance of patient autonomy and the destructive power of physician paternalism (Kliever 1989). This case and others like it challenged the widely held view that because sick patients do not have as much information about their health as do their doctors, they are not rational enough to make health-care decisions on their own behalf. The overriding ethos prior to this time was that patients should be treated with paternalism and the benevolent protection provided by their wiser, more experienced physicians (Beauchamps and Childress 2009), but from this time forward both legal and medical decision making moved steadily toward a more patient-centered approach.

In the 40 years since cases like Dax Cowart's came to the public's attention, principles of patient autonomy and self-determination have become hallmarks of legal jurisprudence. These principles depend on the notion that if

patients have the cognitive capacity to make their own decisions, such decisions must be protected. The legal and moral systems governing patient care were thus forced to determine the standards by which such capacity would be assessed (Strasser 1995). Cases like Cowart's challenged the notion that pain and illness rendered patients incapable of decision making, and legal mandates focused attention on the issue of informed consent (*Canterbury v. Spence* 1972). Informed consent shifted the burden of treatment decisions to the patient, while the responsibility to provide complete information was imposed upon the treating physician. *Canterbury v. Spence* held that physicians must reveal information that a "reasonable person" would likely find significant when determining whether or not to accept the proposed treatment. This ruling held that the standard for measuring the duty to disclose is that such disclosure must be reasonable but also as complete as possible under the circumstances. Although the physician was not required to disclose every conceivable risk, he or she was bound to provide information that might prevent the patient from pursuing the treatment in question, including potential risks, pain, and disability.

During the 1970s and 1980s questions regarding informed consent concerned the ways in which a patient's desires regarding his or her own treatment could be determined in cases in which the patient has lost the capacity to articulate such determinations on his or her own behalf. Given advances in medical technology, some unconscious patients could be kept on life support indefinitely. Decisions about withdrawal of treatment took on new significance and were more complicated when they involved an unconscious patient. Again, various high-profile cases sparked intense legal, personal, and public debates. One of the first of these media-fueled cases to gain public notoriety was that of Karen Ann Quinlan.

KAREN ANN QUINLAN: SURROGACY AND TREATMENT WITHDRAWAL

After Karen Ann Quinlan collapsed at a party, friends and fellow partygoers put her to bed but then found her unconscious and without respiratory function 15 minutes later. Emergency medical personal were able to restore her heartbeat and breathing, but she remained unconscious. Over the next several months Quinlan fell into a persistent vegetative state—a permanent unconsciousness characterized by irreversible cessation of cognitive functions of the cerebral cortex, although brainstem functions, such as breathing and heart rate, remain intact (Laureys et al. 2004). Quinlan's parents and appointed guardians, Joseph and Julia Quinlan, wanted to remove their daughter from the ventilator that was believed necessary to sustain her life. The Quinlan's argued that they knew Karen Ann's wishes better than any member of the hospital staff—none of whom had known Karen Ann in a conscious state. Her parents testified that their daughter would not wish to be artificially sustained using "extraordinary measures," and requested that she be removed from the ventilator (Angell 1993). Local officials threatened to bring homicide charges against the Quinlans and the hospital if the ventilator was removed (Cawthon 2004). The Quinlans sued.

Although the Quinlans lost in District Court, the New Jersey Supreme Court issued a ruling declaring that when the wishes of an adult regarding his or her care can be established, that individual's wishes must be upheld. However, the process to use in establishing those wishes—even with an advance directive—remained unclear. In Quinlan's case her parent's fight to remove Karen Ann's respirator became a pyrrhic victory; although the respirator was removed after the New Jersey Supreme Court ruling, Karen Ann was able to breathe on her own and survived in a vegetative state for nine additional years. The questions in this case were reintroduced to public debate through another tragic case involving another young woman.

NANCY CRUZAN: SURROGACY AND "CLEAR AND CONVINCING EVIDENCE"

In January 1983, 25-year-old Nancy Cruzan lost control of her car, overturned, and was discovered lying face-down in a ditch without detectable respiratory or cardiac function. She was estimated to be oxygen deprived for 12 to 14 minutes. Emergency medical technicians were able to restore her breathing and heartbeat. Cruzan remained in a coma for approximately three weeks and then progressed to an unconscious state in which she was able to orally ingest some nutrition. In order to ease her feeding and further her recovery, surgeons implanted a feeding and hydration tube, and she was admitted to a state hospital. However, subsequent rehabilitative efforts proved unsuccessful. It became apparent that Cruzan had virtually no chance of regaining her mental faculties. Her parents and appointed guardians, Lester and Joyce Cruzan, asked the hospital to terminate nutrition and hydration procedures. The hospital refused to honor the request without court approval.

The court decisions involving the Cruzans' battle with the State of Missouri are long and complex. Missouri argued that (1) although Cruzan was in a "persistent vegetative state," she was neither dead within the meaning of Missouri's statutory definition of death nor terminally ill, and thus her treatment was of "compelling interest" to the state; (2) Cruzan's right to refuse treatment did not outweigh Missouri's strong policy favoring the preservation of life; (3) conversations with her friends and family members concerning her desire to not "be placed on machines," unless she "could live at least halfway normally" were unreliable for the purpose of determining her intent, and were thus insufficient to support the parents' claim to exercise substituted judgment on her behalf; and (4) no person could terminate medical treatment for an incompetent person in the absence of "clear and convincing, inherently reliable evidence" of the incompetent's wishes, which they held was absent in Nancy Cruzan's case (Cawthon 2004).

The U.S. Supreme Court (*Cruzan v. Director, Missouri Department of Health* 1990) found that due process was not violated by Missouri's requirement that an incompetent person's wishes to withdraw life-sustaining treatment be *proved by clear and convincing evidence*, and that states were free to establish their own evidentiary standards regarding treatment withdrawal when patients are unable to articulate their own health-care decisions. In Cruzan's case, the testimony of additional witnesses ultimately satisfied Missouri's requirement that clear and convincing evidence of her wishes *did* exist, and medically assisted nutrition and hydration were terminated.

Although the ruling in *Cruzan v. Missouri* seemed to be a setback for the "Right-to-Die Movement," it resulted in a number of important precedents that ultimately benefited the movement. It also raised new questions. Most importantly, the Supreme Court determined that the standards for surrogacy are to be established by the state. Following *Cruzan*, nearly every state passed statutes that outlined the ways in which surrogates would be appointed and how decisions regarding patient care would be made. Following the Quinlan precedent, most states determined that the wishes of the patient—when they can be established—are paramount for surrogate decisions. Furthermore, most states determined that surrogate decision making ought to be performed by the people most likely to know the patient.

Another significant issue emanating from the *Cruzan* case was that the assisted nutrition and hydration was determined to be a form of health care, and like all other forms of health care, it can be refused and withdrawn if its delivery is against the will of the patient, whether this refusal or withdrawal request is issued by the patient or by the proper surrogate.

UNIFORM HEALTH-CARE DECISIONS ACT

Given that the Supreme Court had determined that questions concerning the identification of a surrogate decision maker and the standard of evidence used to determine the authority of these agents was a matter for states to decide, states sought a uniform means of answering these questions. In 1993, in an effort to assist states in adopting a clear standard, the National Conference of Commissioners on Uniform State Laws produced an act intended to address the problem of determining who has the authority to make health-care decisions (including the cessation of life-sustaining treatment) when the patient lacks this capacity. The resultant Uniform Health-Care Decisions Act (UHCDA) applies to health-care decisions for adults and emancipated minors. The act holds that any adult or emancipated minor with capacity may give oral or written instructions to a health-care provider, and these instructions remain in force in the event that the individual loses capacity. This act further provides for the appointment of a surrogate, either through a durable power of attorney for health care or other state-approved document signed while the patient has capacity. If the patient has not signed a formal document giving decision-making authority to a chosen individual, the act recommends a priority list of those authorized to assume this authority. The act recommends that this power first be given to a spouse, if one exists, then to an adult child, then a parent, and then to the patient's parents or to the patient's adult siblings. In the absence of such person(s), the act states that "an adult who has exhibited special care and concern for the patient, who is familiar with the patient's personal values, and who is willing and able to make a health-care decision for the patient," may assume the authority (National Conference of Commissioners on Uniform State Laws 1993). In the event nobody qualifies as a surrogate, the health-care provider may turn to an appropriate court for an appointment. Most states have adopted some version of this act, often with changes to the priority list. Nearly every state favors persons who are legally related to the patient.

Under this act, and in resulting laws adopted by most states, surrogate decision making is to be governed by the "substituted judgment standard." According to this standard, the decisions of surrogates must be in accord with the expressed preferences of the patient before becoming incapacitated (if these are known), and/or made by a surrogate who knows the patient well enough to determine what he or she would decide if he or she had the capacity to make the choice. The substituted judgment standard is to be used if the patient has ever had decision-making capacity. A second standard, "best interest standard," requires that when the wishes of the patient cannot be clearly determined, surrogates are to consider "what would a reasonable person choose" when determining what is best for this patient under these circumstances. It is the responsibility of a surrogate to first uphold the wishes and values of the patient rather than the surrogate's own wishes and desires, and to consider external factors such as community understandings of the patient's "best interest" only when the patient's own values and desires are impossible to establish. Finally, when it is impossible to ascertain the patient's own values, the UHCDA recommends a strong preference for life-sustaining procedures, and holds the preservation of life as central in determining "best interest."

The UHCDA clearly outlines procedures to follow when an individual lacks capacity to refuse or consent to medical treatment. The determination of incapacity, however, is usually left to treating physicians or consulting psychiatrists. These determinations require an assessment of four functional abilities: (1) the ability to express a choice, (2) the ability to understand information relevant to treatment decision making, (3) the ability to appreciate the significance of that information on one's own medical situation, and (4) the ability to reason with relevant information and logically weigh treatment options (Grisso and Appelbaum 1998). Quinlan and Cruzan (and Schiavo, below) clearly lacked an ability to express a choice. Dax Cowart retained this ability as well as an ability to understand medical information, to logically weigh options, and apply those options to his unique situation. The ability to understand information requires that information is received as presented by

medical providers and that it is comprehended. This ability is most commonly impaired by cognitive disorders (e.g., dementia, intellectual disability, delirium). The ability to appreciate information in regard to one's situation requires a recognition and acceptance of one's medical condition(s). In end-of-life decisions, it requires understanding and acceptance of one's own impending death. Finally, the ability to reason and logically weigh treatment options requires that a patient is able to understand the benefits and risks of the possible treatment options, including consequences of possible failure of the proposed treatment, and to choose an option based on personal preference.

THERESA MARIE "TERRI" SCHIAVO: SURROGACY AND WITHDRAWAL OF NUTRITION AND HYDRATION

The public controversy over end-of-life decisions did not end with the UHCDA. Public misunderstanding of these issues was particularly evident in the Terri Schiavo case, which dominated the news in early 2005 until Terri's death on March 31, 2005. On February 25, 1990, Terri Schiavo suffered oxygen deprivation as a result of a cardiac arrest brought about by eating disorder-induced hypokalemia. Less than a year later, Terri's attending physician declared that she was in a persistent vegetative state. It was not until 8 years after Terri's collapse that her husband and surrogate, Michael Schiavo, requested the removal of the feeding tube that was sustaining Terri's life. He argued that Terri herself had made statements after seeing media coverage of the Karen Ann Quinlan case such as "I wouldn't want to be kept alive on machines."

The *Schiavo* case resulted in numerous trials and hearings; it was heard by the Supreme Court of Florida and considered, but ultimately rejected, as a suitable case by the U.S. Supreme Court. A Florida law was passed in response to her case ("Terri's Law") as was an act of Congress, Act for the Relief of the Parents of Theresa Marie Schiavo (Public Law 109-3); her feeding tube was withdrawn and reconnected twice. It was removed for the third and final time on March 18, 2005.

The controversy concerning Terri's case revolved around two issues: (1) whether her husband, Michael Schiavo, was her proper surrogate (as opposed to her parents, Robert and Mary Schindler, who wished to continue Terri's treatment) and (2) whether nutrition and hydration constitute "standard medical care" (rather than "basic care") and thus, like any other medical therapy, can be withdrawn by the proper surrogate decision maker. The Florida Supreme Court upheld the standards outlined in the UHCDA: the spouse of the patient was considered the rightful surrogate called on to interpret the patient's wishes; any treatment that violates the wishes of the patient receiving that treatment can be withdrawn; and while the preservation of life should be the preference in cases where the patient's wishes cannot be established, the patient's own wishes (even if interpreted through a surrogate decision maker) are the final arbiter of whether or not life-sustaining treatment should be continued.

WITHDRAWAL OF TREATMENT, EUTHANASIA, AND PHYSICIAN-ASSISTED SUICIDE (PAS)

Many who opposed the removal of Terri Schiavo's feeding tube charged that discontinuing nutrition and hydration was tantamount to euthanizing a patient; however, the court rulings in this and other cases consistently demonstrate that a bright line exists between euthanasia and treatment withdrawal, a line that is generally understood to be the distinction between letting die (in the case of treatment withdrawal) and killing (in the case of active euthanasia).

Euthanasia is derived from the Greek language; its definition involves a "good" or "easy" death. In its literal translation euthanasia has no relation to death involving another person. The shift in the meaning of the term to "assisted death" stems from 1969 Netherlands law that allowed doctors to assist in the suicide of terminally ill patients under prescribed and narrow conditions (Gomez 1991). In order to understand the various laws in the United States that govern assisted death, it is essential to understand the distinction between "active voluntary euthanasia," which requires a person other than the patient to participate in the delivery of a life-ending substance, and "voluntary passive euthanasia" (most often referred to as "physician-assisted suicide"), whereby the patient acquires a prescription for medications and then could choose or not choose to use to end his or her life without the active participation of a health-care provider or even the provider's knowledge of the time of death of the patient. Active euthanasia is illegal in all states, whereas physician-assisted suicide (PAS) is currently legal in five U.S. states (Oregon, Washington, Montana, Vermont, and California).

The first attempts to legalize assisted suicide through voter initiative were defeated in Washington State in 1991 and in California in 1992. In 1997, two landmark U.S. Supreme Court rulings reignited the controversy surrounding PAS by opening up the possibility that states could institute the practice. In *Vacco v. Quill* the court ruled that New York's ban on PAS was constitutional, that the state had the authority to ban the practice, and that there exists no constitutional guarantee of a "right to die." In *Washington v. Glucksberg* the court ruled that because assisted suicide is not a fundamental liberty, it is not protected under the Fourteenth Amendment. However, even though the Supreme Court ruled against a constitutional right to die in both cases, these rulings were a victory for those who favor assisted suicide, because although the court found that states could make assisted suicide illegal, the court also made it clear that states could legalize assisted suicide if they so choose. As a result, the question of the legality of assisted suicide was to be decided by the states.

In 1994, proponents of legalization successfully launched a referendum in Oregon to make PAS legal. For 3 years,

the law was blocked by Oregon courts and did not take effect. In October 1997, following the rulings in *Vacco* and *Washington,* the Supreme Court refused to hear a case brought by groups who wished to challenge the constitutionality of Oregon's law, effectively upholding the law. In October 1997, opponents of the law launched a referendum to repeal the law, but voters rejected this attempt at repeal.

Following Oregon's lead, Washington State enacted nearly identical legislation in 2008, and Vermont followed suit in 2013. Montana also permits PAS as a result of a state Supreme Court ruling in *Baxter v. Montana* (2009) that held that terminally ill patients had a right to a lethal prescription from their physicians under the state's constitution. Although the details of Montana's law have not been carved out and will likely confront challenges in the form of proposed voter referendums, the restrictions and allowances for PAS are clearly outlined in Oregon's plan that was enacted nearly verbatim in both Washington and Vermont. Oregon's Death with Dignity Act requires that patients requesting a prescription capable of resulting in death must be terminally ill with a projected death within 6 months, the terminal diagnosis must be confirmed by two physicians, the patient must have informed his or her family, the patient must undergo screening for depression if medically indicated, and the patient must make two separate and documented requests (Oregon Death with Dignity Act 1994). The patient can withdraw the request at any time. Both Oregon and Washington State issue annual reports concerning the exercise of PAS in their state. The most recent information provided by these states indicates that far more requests are issued than acted on by the patients, and the patient demand for PAS has been consistently lower than original predictions (Oregon Public Health Division and Washington State Department of Health). According to the data provided by these states, patients requesting PAS have not been the poor and disabled as originally feared; most have been middle-class men. The majority have received a diagnosis of terminal cancer (Trice-Loggers et al. 2013). The most frequently stated reason for pursuing this intervention is a desire to exercise individual autonomy in the timing and method of their impending death (Oregon Public Health Division 2015).

PALLIATIVE CARE: SCOPE, LIMITATIONS, AND PAS

One of the central practical concerns raised by the medical community regarding laws that permit PAS is that this practice will limit the advancement of palliative care. Suffering manifested by pain, inability to pursue life goals, and isolation from social support are genuine concerns for patients and their families. Although the hospice movement and increasing support for palliative care programs at medical institutions has attempted to respond to these concerns, studies continue to demonstrate that intractable pain is poorly treated in the United States, and advocates for PAS suggest that such suffering necessitates the need for assisted suicide (Cantor and Thomas 2000). The doctrine of "double effect" (the notion that the use of analgesics is legitimate, even if such interventions shorten the life of the patient) is well supported in law. Physicians are not subject to malpractice liability, legal sanction, or professional discipline, provided their use of analgesics is within good faith practice guidelines. Although purposefully causing a patient's death through use of medications is considered active euthanasia and constitutes homicide, some risk taking in relieving patient suffering is considered acceptable medical practice. "The risk of death is justified, not because it is intended but because there is no alternative approach that makes the risk of death less likely and the alleviation of suffering possible" (originally quoted by Cantor and Thomas 2000; Fleischman 1998). Moreover, it is now widely accepted that pain itself shortens the life of the patient; thus, the relief of suffering is justified as a better alternative than allowing the patient both to bear pain and to permit the hastening of death as a result of that pain (Fohr 1998).

"Terminal sedation," sedation that results in unconsciousness through the remainder of the dying process, is more controversial and legally ambiguous (Quill et al. 1997). This practice walks a fine line between euthanasia and palliation and is widely seen as the palliative therapy of last resort (Quill and Byock 2000; Omipidam 2013). The use of analgesics to maintain a comatose state has some degree of legal protections. Physicians can prescribe analgesics for pain relief, even if the treatment poses some risk to the patient—ultimately there is little difference between doing so and performing a surgery that poses risk but simultaneously provides hope of recovery or pain relief. However, terminal sedation requires professional oversight, which calls for the risk associated with the practice to be in proportion to the intended benefit and demands that increased use of these medicines be titrated with great care and professionalism (de Graeff and Dean 2007).

WITHDRAWAL OF INEFFECTIVE TREATMENT

Perhaps the most controversial developing issue at the intersection of law and death is whether and when treatment may be considered "futile" or "ineffective" by the health-care provider such that it is acceptable to withdraw further treatment against the wishes of the patient or surrogate decision maker (Rubin 1998). Although many states are considering or instituting "futile care policies," Texas was the first state to formally institute legislation, the Advance Directives Act, in 1999. Since its institution, health-care providers can withdraw "futile treatment" once the patient or substitute decision maker is given a 10-day advance notice. However, controversies remain as to what constitutes futility, how the goals of treatment are to be determined, and who should decide these questions. Physicians can refuse to deliver treatment that does not serve to meet the medical needs of a patient, even if the patient or surrogate demands it. It may be considered malpractice to continue therapies that serve no medical purpose—indeed physicians have been sued for

continuing expensive, ineffective treatments from which they profit. Nevertheless, physicians are more inclined to continue treatments such as dialysis or mechanical ventilation, even when these treatments have no hope of restoring the patient's function or helping that patient to meet his or her life goals. Families often contend that continuing the patient's life, even in a comatose, minimally conscious, or vegetative state, serves the patient's and family's goals.

The Texas law provides for the hospital and/or physician to refuse to continue treatment deemed medically ineffective, but only under narrow and prescribed conditions. Physicians and institutions must perform thorough reviews of the case, consult the hospital's standing ethics board, and attempt to reach a mutually agreeable treatment plan with the family. If the dispute continues after a waiting period, a second, ad hoc committee should be formed to review the case. If this second committee concurs that the treatment in question is indeed ineffective, the physician and institution must attempt to transfer the patient to another facility to deliver the requested treatment (Texas 1999). The final determination to withdraw treatment, despite the wishes of the patient or surrogate, can only be made if all of these options fail to mitigate the dispute. Furthermore, this law exempts the provider from criminal or civil prosecution.

BRAIN DEATH AND THE WITHDRAWAL OF TREATMENT

Unlike persistent vegetative states (PVSs) and other comatose states whereby part or all of the brain remains functional, brain death is the total and permanent cessation of the function of the whole brain. Simply put, brain death constitutes the death of the patient, whether or not other bodily functions such as breathing and cardiac function can be maintained artificially. The term *brain death*, used as a means to separate neurological death from death via cardiac arrest, was defined, in part, as a means of helping to identify potential organ donors whose cardiac and other functions may need to be maintained for the sake of organ procurement (Troug and Robinson 2003; Truog and Miller 2008). Because "the dead donor rule" requires that organ procurement cannot be the cause of the patient's death, a clarified notion of neurological death was necessary to determine the conditions under which organs can be procured despite the continuation of mechanical interventions intended to preserve perfusion of the organs until they can be harvested (Truog and Miller 2008; Sade 2014). Given that persons who have been declared dead according to neurological criteria are in fact dead, there is no legal obligation to continue to maintain their organ function via artificial means, regardless of the desires of the deceased's family. However, few people understand the criteria for neurological death. Most in the general public confuse brain death with PVS and do not understand that the person declared brain dead can never regain any form of neurological function (Truog and Miller 2008; Caplan et al. 2014).

Recent cases have fostered further confusion in the public sphere concerning this form of death. In the winter of 2013, 13-year-old Jahi McMath suffered brain death due to oxygen deprivation during an operation to remove her tonsils and trim her palate. Her family refused to accept her death and insisted that their daughter remain on respiratory and cardiac support. The hospital initially complied with this request, which reinforced the family's view that their daughter was not dead and that her life was being maintained on life support. The family sued Children's Hospital and Research Center in Oakland, California, contending that removing Jahi from mechanical support would result in her "death," despite the fact that the coroner had already issued a death certificate (Gostin 2014). The district court of San Francisco ordered a stay that required the hospital to continue treatment until a trial could be held. Ultimately, the court ruled that if the family could find a facility willing to admit the girl and perform the tracheotomy necessary to maintain her in her current state, Jahi would be transferred at the family's own risk. The family eventually moved her to an undisclosed facility in New Jersey, one of two states (the other being New York) that permit religious exceptions to the Uniform Declaration of Death. As of this writing Jahi McMath remains on mechanical support.

SUMMARY

The questions concerning death, dying, and the law seem to revolve in large part around the high-profile cases that bring the questions to public consciousness. Even questions that appear to be settled, such as the right to treatment withdrawal, the status of nutrition and hydration as medical treatment, and the definition of death, remain open to debate and will likely face future court and legislative challenges. PAS, in particular, will likely expand to additional states within the next decade.

Many jurisdictions are encouraging their citizens to identify a medical proxy and discuss their desires concerning end-of-life treatment with their loved ones. Legislation concerning the right of institutions to refuse to deliver ineffective treatment is also becoming increasingly attractive in some places, with several states considering bills to limit physician and institutional obligations to follow the mandates of family members when continued treatment is deemed to be medically ineffective and/or counterindicated. Thus questions concerning death, dying, and the law are continuingly evolving and seemingly constantly dependent on the individual cases that raise new concerns in the public imagination.

SUMMARY KEY POINTS

- The evolution of legal decisions regarding death and dying has been shaped by cases that have garnered widespread media and societal interest.
- Legislative actions have sought to prevent legal controversies by establishing procedures to be followed when a patient lacks the capacity to make treatment decisions regarding end-of-life care.
- There is a growing trend toward identifying surrogate decision makers for end-of-life care decisions, and these decision makers commonly utilize a substituted judgment model.
- Many jurisdictions are recognizing the right of a health-care provider to refuse to provide treatment that will be medically ineffective, even if such treatment is desired by the patient or a surrogate decision maker.
- The "right-to-die" movement has made significant gains in the last 20 years, culminating in the legalization of physician-assisted suicide in five of the United States.

Role of the psychiatric evaluator in child custody disputes

STEVEN J. CIRIC AND STEPHEN B. BILLICK

INTRODUCTION

The role of the psychiatric evaluator in child custody cases is challenging and complex. There is high demand for competent psychiatric evaluators, given a substantial divorce rate in the United States, custody disputes arising between unmarried parties, and the frequency of litigation. Figures from the National Center for Health Statistics suggest a divorce rate above 50%, citing 3.6 divorces and annulments versus 6.8 marriages per 1000 population (Centers for Disease Control and Prevention 2014). The high number of divorces and separations affects more than one million children each year, and approximately 10% of divorces involve litigation over custody or visitation (Bernet 2002). Conflicts between unmarried parties include cohabiting, single, and noncustodial biological parents; grandparents; and the impact of reproductive technologies, surrogate childbearing, and DNA testing for paternity.

GOAL OF CHILD CUSTODY EVALUATIONS

The overall child custody goal for children in separation and divorce is to try to achieve 50%/50% or the optimal degree with their parental figures of attachment. When not initially possible, the evaluator should recommend approaches toward this goal. Child custody recommendations should never be punitive but made in the best interests of the child, e.g., supervised visitation. From the child psychiatric perspective, helping an inadequate or harmful parent to develop healthy interaction with both the children and the custodial parent is the ultimate goal, whenever possible.

IMPACT OF DIVORCE ON CHILDREN

The psychological impact of divorce on both children and parents can be far-reaching, so that a competent and thoughtful child custody evaluation may diminish future ill effects. While the divorce process on children is not automatically pathogenic, and most controlled research underscores the resilience of most children to "bounce back" from the stress of divorce (Emery and Coiro 1995; Hetherington and Stanley-Hagan 1999), other evidence possibly points to a greater risk for psychological problems. For instance, Wallerstein et al. (2000) cited national studies that demonstrate children from divorced families have more depression, learning, and interpersonal problems, and utilize more mental health services into adulthood.

Reanalyzing three decades of data from the New York Longitudinal Study of Chess et al. (1983), Shaw et al. (1993) conducted a prospective examination of parental functioning and children's adjustment *before* divorce, and found no consistent differences between children from to-be-divorced and always-married families. However, they did find a consistent predictor of the children's poor adjustment following divorce was parental conflict prior to divorce. Boys showed more post-divorce behavioral difficulties than girls, which was consistent with prior research (e.g., Zaslow 1988; Wallerstein 1991). The authors suggested this might involve the boys' loss of daily contact with their fathers. Wallerstein (1991) suggested the observed gender difference may involve a "sleeper effect" for girls, who go on to experience interpersonal problems in young adulthood. Emery et al. (2005), citing a meta-analysis in 1999 by Amato and Gilbreth, suggested the amount of contact between child and nonresident father is a poor predictor of the child's psychological well-being, and a father's payment of child support has greater impact. Lahey et al. (1988) reported a significantly higher incidence of parental Antisocial Personality Disorder in divorced families with boys who developed conduct disorder, giving rise to the consideration of a genetic vulnerability contributing to both parental marital discord as well as post-divorce maladjustment in the child. This viewpoint was supported in subsequent research (Jocklin et al. 1996).

The adverse effects of divorce on children have been discussed extensively by Wallerstein and Kelly (1980) and

Wallerstein et al. (2000). In 1971, Wallerstein and her colleagues embarked on a nonrandomized, noncontrolled study of 131 children going through separation and divorce with interval assessments between 18 months and 25 years post separation. Half of the children had difficulties during the first year after divorce and prolonged post-divorce maladjustment was associated with high levels of parental discord, parental mental illness, poor pre-divorce parenting, and a custodial parent burdened by emotional, physical, social, or economic stresses. Wallerstein et al. (2000) further observed that many of the post-divorce children from the longitudinal study, now adults, experienced relationship difficulties of their own.

Meta-analysis by Bauserman (2002) found that children in joint physical or legal custody were better adjusted than children in sole-custody settings, comparable to children in intact families. Stover (2013), citing Goldstein et al. (1996), noted that infants and younger children may benefit from more frequent contact with noncustodial parents. Evidence suggests that when a divorce is associated with a move to a less stressful situation, children in divorced families are similar in adjustment to intact families with nondistressed marital relations (Hetherington 1999). Emery et al. (2005) also discussed this "relief hypothesis" following parental separation in high-conflict marriages.

HISTORICAL PERSPECTIVE

Changes in custody decision making have evolved with recognition of the rights of children and women, shifting legal emphasis toward individual rights and equal protection, and given research in child development and attachment. Derdeyn (1976) wrote that in ancient times, "the father had absolute control over his children and could will or condemn them to death with impunity." For many years in England and the United States, children were considered to be chattels, the property of the father without their own rights (Sadoff and Billick 1981; Solnit and Schetky 1986).

The tender years

Following the British Act of 1839 advanced by Thomas Noon Talfourd, the "tender years doctrine" became the primary standard for determining child custody, concurrent with the women's rights movement of the late nineteenth and early twentieth centuries. This doctrine presumes a unique and optimal relationship between mothers and infants, consistent with infant attachment and psychoanalytic theory (Kelly 1994). Sadoff and Billick (1981) discussed how the doctrine introduced the psychiatrist and psychologist into the domestic relations court to present expert testimony regarding outcomes of parent–child relationships and child development. The "tender years doctrine" eventually expanded to include all children and led to mothers gaining custody in greater proportion to fathers.

The best interests of the child

The "best interests of the child" standard, which guides most custody decisions today, arose with increasing recognition of the rights of children and changing judicial attitudes. In the landmark case of *Painter v. Bannister* (1966), the Iowa Supreme Court held in a custody dispute between a child's father and maternal grandparents that "the primary consideration is the best interest of the child." The justices determined that the child, whose Iowa-born mother had died in a car accident, was to remain in the custody of his stable and Midwestern grandparents rather than return to his remarried, California-born, and "Bohemian" father. In *Watts v. Watts* (1973), a New York State Family Court held that maternal preferred custody statutes (embodiments of the "tender years doctrine") violated fathers' equal protection rights under the Fourteenth Amendment (Kelly 1994).

The model Uniform Marriage and Divorce Act, proposed by the American Bar Association in 1970, further established the "best interests of the child" standard as well as consideration of continuity in parenting, the quality of the parent–child relationships, the physical and emotional health of all parties involved, and a child's wishes if he or she is deemed to be of sufficient age and capacity to form an intelligent preference.

Goldstein et al. (1979) critiqued the "best interests" standard and suggested the less sanguine language of "least detrimental alternative" as a more realistic standard that appreciates the inevitable harm to a child in any divorce. Another criticism is that the standard is too vague, subjective, and prone to judicial bias and acrimonious litigation. Concern that the standard may force women to trade off spousal and child support to secure custody has not been demonstrated in research (Kelly 1994).

The "best interests" standard places the rights of the child above the rights of parents in custody determinations, and should theoretically eliminate judicial discrimination on the basis of a proposed custodian's gender, sexual orientation, and physical or psychiatric disability (to the extent that these factors do not bear on the individual's relationship to and ability to care for the child). Although potential for bias always exists, as in the study by Raub et al. (2013) suggesting court decisions around custody and visitation in high-conflict divorce correlate to parental income, courts rely ever more on psychological factors, and the "best interests" standard allows judges more flexibility.

WHEN AND HOW PSYCHIATRY BECOMES INVOLVED IN CUSTODY DISPUTES

Sources of requests for evaluations

The psychiatric evaluator in the separation/divorce process may be asked to give opinions on custody, visitation, and psychiatric treatment needs of parents or children. Waller and Daniel (2005) elucidated factors that may commonly prompt a custody evaluation, including sexual or physical

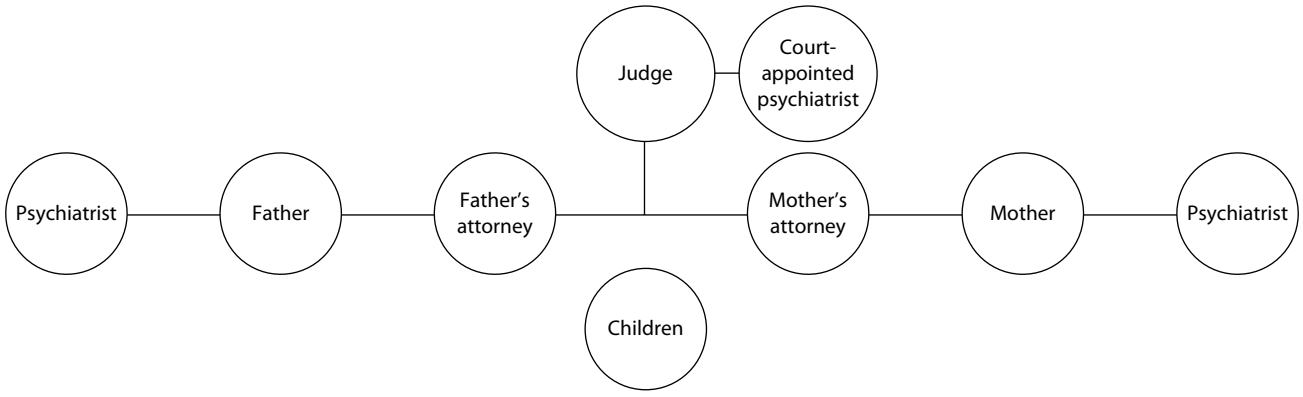

Figure 38.1 Traditional view.

abuse allegations, questions of parental fitness (e.g., mental illness or substance use), parental conflict, alienation issues, domestic violence, relocation, remarriage, parental sexual orientation, and grandparent or adoption issues.

An evaluator may respond to requests from both parties for a clinical consultation only, in an effort to reach a parenting agreement. Parents who favor the consultation room over the courtroom may be more amenable to reaching a mutual agreement (Levy 1985a), and courts in general acquiesce to parental agreement: the parents consent and the state assents (Despert 1953).

When only one party to a custody dispute pursues a psychiatric evaluation, the evaluator should request to interview both parties involved, though the other parent might be uncooperative out of fear the psychiatrist is biased. The evaluator should be aware of pressures for a favorable decision and remain "child-centered and child-oriented" rather than parentally driven, consistent with training in child and adolescent psychiatry.

When the court orders an independent evaluation, or when two opposing attorneys agree on one psychiatric evaluator, parents may be less amenable to a mutual decision, but it is easier for the psychiatrist to maintain parental neutrality, resist adversarial pressures, and represent the "best interests of the child" (see Figure 38.1).

A psychiatric evaluator may also be retained by a *guardian ad litem,* an attorney appointed by the court to represent the child and not one parent or the other. Judges and parents' lawyers sometimes pay more attention to parental concerns, so an active *guardian ad litem* is in the best position to utilize the psychiatrist's recommendations in court to advocate for the child's "best interests" (see Figure 38.2).

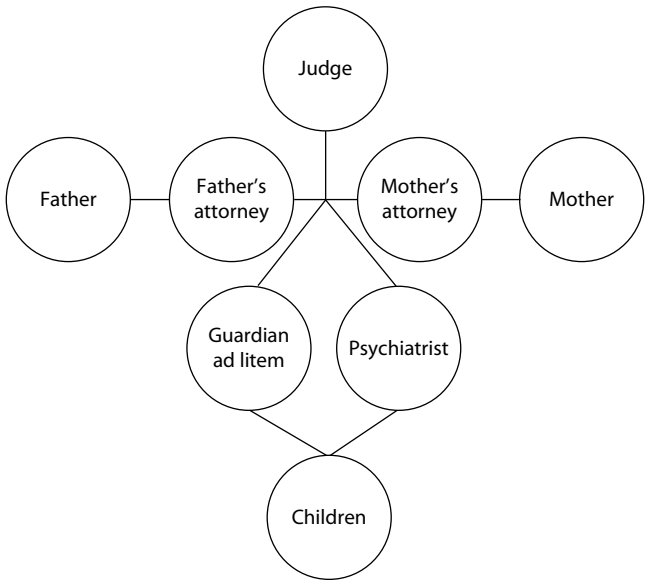

Figure 38.2 Preferred situation.

Mediation

Divorce mediation, an alternative to acrimonious and costly litigation, is a forum where all parties work together to reach mutual resolution (Ruman and Lamm 1985). Although the psychiatrist often has the same advantages as when providing clinical consultation, mediation is a legal process and usually involves one attorney and one psychiatric evaluator. Both are expected to be impartial to the needs of the parents, and the psychiatrist, of course, maintains the position of child advocate. California's Code of Civil Procedure (1984) marked the first state ruling mandating mediation attempts to resolve custody decisions before proceeding to litigation, and the federal government (e.g., Alternative Dispute Resolution Act of 1998) and other states subsequently adopted similar procedures. Mediation decreases burden on the judicial system and may be more sensitive to the emotional needs of parents and children. Dillon and Emery (1996) surveyed parents nine years after random assignment to mediation or litigation. The mediated families saw increased visitation, interparental communication, and noncustodial parent involvement. Emery et al. (1994) followed families for 1 year after similar random assignment and found fathers were more satisfied with mediation and more likely to cooperate with child support payments. Mothers were more satisfied with litigation, noting over 90% of the litigated custody cases ended in sole maternal custody. Maccoby and Mnookin's (1992) study of about 2000 divorcing California families found mandatory mediation to result in slightly higher instances of joint custody, though mediators were actively making this recommendation. In contrast,

Reynolds et al. (2007) analyzed all mandatory mediation outcomes in a North Carolina judicial district in 2002 and found no increase in the incidence of joint physical custody relative to litigation; in fact, mothers received sole custody more often. The authors suggested that mediators in North Carolina followed a best practice of refraining from a dual role of rendering custody recommendations to the court when mediation failed, and the mediation proceedings were confidential and privileged. Krauss and Sales (2000) commented that while some states require mediation efforts or favor joint custody, neither has been confirmed by empirical research to improve the outcomes of divorce for children and parents.

Visitation

When joint custody is not possible, visitation becomes especially important to minimize the child's sense of loss from divorce and encourage the natural affectionate bonds with both parents. Some researchers have suggested frequent overnight visitation with a nonresidential parent may result in attachment insecurity with the residential parent (Tornello et al. 2013), but this remains controversial. Warshak (2014) argues that valid and reliable research favors allowing children under 4 years old to be cared for at night by each parent, without jeopardizing the children's development. However, when visitation decisions are complicated by accusations of abuse or neglect, the psychiatric evaluator has the additional responsibility of assessing the validity and extent of the allegations, and considering restriction (e.g., daytime only or supervised) or denial of visitation when doing so would be in the child's best interests.

CONDUCTING THE PSYCHIATRIC EVALUATION

Training

In order to conduct a thorough and competent child custody evaluation, adequate training, ideally in child psychiatry and forensic subspecialty fellowships, is critical. The American Psychiatric Association (APA 1982) has recommended that the general psychiatrist undertaking custody evaluations consult with a child psychiatrist, when available, and that novice evaluators first sit in on several child custody cases to observe the process thoroughly before beginning their own evaluations. The psychiatrist should have knowledge of basic family law, including statutes and relevant case law in the jurisdiction of the evaluation (e.g., legal presumption in favor of joint custody) (AACAP 1997). Provided adequate training, any psychiatrist doing a competent and thorough psychiatric child custody evaluation, regardless of the source of payment, should arrive basically at the same final decision.

Role as evaluator

Solnit and Schetky (1986) reminded that the psychiatrist must always maintain the role of advocate for the child's best interests, parental neutrality, and not slip into role of therapist for a given party. As child advocate objectively applying the examination data to the appropriate legal standard, the forensic psychiatrist does not necessarily support what the child *wants*, but what the child *needs*. Ultimately, legal decisions of custody are always made by the court. The evaluator must try to conduct as prompt an evaluation as possible, as protracted evaluations can bring further stress on the child.

The interviews

A large part of the psychiatric evaluation in child custody cases consists of a series of interviews gathering careful parental and child histories from these primary sources. The evaluator first obtains a signed waiver of confidentiality from all parties to be interviewed, distinguishing the forensic evaluation from the psychiatrist's work of therapy, as it may become necessary to disclose findings to opposing attorneys and in court. Usually interviews include each parent individually, each child alone, the child with each parent individually, and sometimes the parents together without the child, the child together with both parents, or the child with his or her siblings. Conducting so many interviews can be time consuming, and the use of a team approach has been advocated (Ash and Guyer 1984; Weiner et al. 1985), but this is not always possible and many psychiatrists do successfully conduct the evaluation alone.

The examination

According to the American Psychiatric Association (1982), there are three major questions that should be addressed during the course of the evaluation:

1. What is the quality of the reciprocal attachment between parent and child?
2. What are the child's needs and the adults' parenting capacities?
3. What are the relevant family dynamics at play?

Levy (1985a) added a fourth primary question: What is the child's preference, if any, for custody?

To address these questions, the evaluator enquires about the extent of involvement each adult has with the child, directly observes interactions of parent with child, and attempts to establish who has the major role of "psychological parent" for the child (Goldstein et al. 1979; APA 1982). This person may not be the genetic parent. Indeed, current research in attachment theory suggests a child's early ties to a primary caregiver who is not the genetic parent result in a superior biological bond between that caregiver and child. Also, the role of "psychological parent" is usually shared by more than one person, for example, both genetic parents or one genetic parent and a step-parent or grandparent. The evaluator may use projective tests, such as drawings, or pose hypothetical questions to the child, to

help determine whom the child relies on most and in what circumstances.

The evaluator may with great sensitivity ask the child directly about a preference for custody, but the reliability of the child's answer is age related. A younger child may express the preference of a parent that he or she is afraid of alienating, rather than express his or her own preference. Adolescent children are more capable of expressing their true desires, but they too may fear hurting the feelings of the parent not chosen. AACAP (1997) wrote that judges may give more weight to a stated preference when the child is 12 years of age or older, and some states actually require the evaluator to ask about a child's preference. Billick (1986) indicated the average 12-year-old has achieved the Piagetian stage of concrete operations and Kohlberg's stage of conventional morality, and suggested juveniles between the ages of 11 and 14 years should be accorded greater latitude in formulating decisions. One may also choose to infer the child's preference through observations.

The evaluator should assess parenting capacities in relation to the developmental needs of the child, including the capacity to provide support and nurturing, and allow appropriate separation and individuation. When joint custody is not possible and there is no clear-cut distinction as to who has the better parenting skills, the evaluator may be forced to make a value judgement, but must remain focused only on the child's development and avoid being swayed by irrelevant biases from attorneys or from within oneself, for example, given a nongenetic, mentally ill, or homosexual parent.

The psychiatrist also must analyze family dynamics and parental motives for seeking custody (e.g., anger, depression, revenge) as separate from parenting issues. The evaluator should also assess the potential custodial parent's ability to promote the relationship of the child with the noncustodial parent, which would favor a positive post-divorce outcome for the child. Finally, the evaluator should be aware of the child's potential involvement in family dynamics. A child may manipulate and influence his or her parents' behavior out of a wish for reunion.

The American Academy of Child and Adolescent Psychiatry (AACAP) *Practice Parameters for Child Custody Evaluation* (1997) detailed important examination factors, including the presence of parental alienation (i.e., where the child has notable, yet irrational, negative feelings toward one parent), each parent's parenting and disciplinary styles, parental physical and psychiatric health, finances, and each parent's family and marital history. The evaluator should explore allegations parents make against each other, but also note whether a parent spends most of the session attacking the other parent at the expense of focusing on the child.

The psychiatric evaluator should ensure the conditions of interviews are optimal, including scheduling of sufficient time for a thorough evaluation and breaks; the presence of attorneys, if required, without interference or uninvited participation; and participation of parents when evaluating a child. AACAP's *Practice Parameter for Child and Adolescent Forensic Evaluations* (2011) suggests the initial participation of a parent is helpful to provide historical information, allow for observation of parent–child interaction, and encourage the child's cooperation, after which it is beneficial to evaluate the child alone.

Collateral sources of information

When conducting the psychiatric evaluation, one may also use a variety of other sources of information, in addition to the previously described interviews. Home visits, where the evaluator can observe the behavior of the child and parents in a naturalistic setting, can be very informative and strikingly differ from the formal office interview setting. Both attorneys involved in the custody battle might have useful information. Other secondary sources of information include teachers, grandparents, pediatricians, or other mental health professionals working with the child or parents. The evaluator, however, should clearly document whether information is from secondary sources or direct observation, as the courts usually place more confidence in primary sources of clinical data.

Confidentiality issues

Malmquist (1994) examined the myriad and diverse ways in which courts regard the issue of confidentiality in custody disputes where one or both parents (or the child) have been, or are presently, in psychiatric treatment. For example, in some jurisdictions, simply entering into a custody dispute essentially puts a party's mental health at issue and automatically waives privilege. In other instances, the court remains guided by the best interests of the child standard and looks to a *guardian ad litem* or independent psychiatric expert to assess whether particular treatment records contain material potentially harmful to the child. Still other courts waive doctor–patient privilege only in cases where there is an allegation of parental unfitness, or rely on an independent psychiatric examination without delving into private treatment records. In the case of *In re Lifschutz* (1970), Malmquist noted the California Supreme Court held "the psychotherapist could be held to answer questions *directly relevant* to the subject of the suit (emphasis added)." Malmquist raised the impractical scenario of clinicians routinely providing quasi-*Miranda*-type informed consent warnings before treating patients who are, or may become, parents, and recommended the disclosure of private treatment records is limited to instances of alleged parental unfitness where the records sought bear directly on parental competency rather than the best interests standard.

The Maryland Court of Appeals, in *Laznovsky v. Laznovsky* (2000), upheld a parent's right to assert doctor–patient privilege in a child custody dispute, noting a constitutional right of privacy and the public policy benefit of protecting the psychotherapeutic process (Caracansi and Billick 2000). However, the court left open the possibility for family court judges to make exceptions in the case of

a parent who claims fitness "without more" (albeit without clarifying the meaning of "without more" or the standard for waiver of privilege).

Children in therapy

This is a potentially wonderful source of additional material about the child. An adept therapist may be willing and able to testify on behalf of the child's best interests, though many are not comfortable with this. Above all, every attempt should be made to avoid disruption of the child's psychological support system and treatment.

Psychological testing

The psychiatrist may wish to consult with a psychologist who is experienced and capable in testing procedures in child custody disputes. AACAP (1997) suggested psychological testing might be most useful when the psychiatric health of a parent or child is a legitimate issue. The Minnesota Multiphasic Personality Inventory-2 (MMPI-2) is considered the most commonly used assessment instrument in the evaluation of child custody litigants (Ackerman and Ackerman 1997; Strong et al. 1999). Medoff (1999) cautioned that clinically significant elevations on MMPI-2 validity scales might indicate underlying psychopathology or empirically associated personality characteristics (e.g., neurotic defensiveness, unrealistic self-image, excessive reliance upon denial), and should not necessarily be explained away by common sense that parents want to present themselves in the best possible light when faced with custody matters. Consistent with normative data for the MMPI-2 in child custody litigation (e.g., Bathurst et al. 1997), Strong et al. (1999) described a method of data analysis that may help distinguish between deliberate attempts to create a positive social image (impression management) and the unintentional concealment of symptoms and areas of maladjustment (self-deceptive positivity).

Billick and Jackson (2007) reviewed psychological testing as an adjunct to the clinical evaluation of parents in child custody cases and favored the MMPI-2 given the high reliability of its validity and clinical scales. The authors noted the Hare Psychopathy Check List-Revised Second Edition (PCL-R) is the superior standard when assessing for antisocial personality defects, but is less practical to administer and importantly lacks validity scales.

Testing data should be used as an adjunct to the comprehensive clinical and forensic evaluation, and not be relied upon in a rote fashion when offering opinions about parental fitness and child custody. Although rating scales have been suggested to aid in the assessment of custody, these are not widely accepted as determinative and should also not be relied upon in making ultimate custody recommendations. Krauss and Sales (2000) cautioned that no actuarial prediction of a child's best interests is possible given the ambiguity of the standard and lack of operationalized outcome variables. Emery et al. (2005) recommended the use of these instruments should be limited to research.

Referrals for treatment

As part of the psychiatric evaluation in child custody cases, the evaluator is also usually obliged to assess the need for psychiatric treatment for parties involved. This is to help assure a favorable adjustment by the child after divorce. Referrals should be made to other therapists to keep the evaluator's role distinct, and treatment recommendations should be realistic.

MAKING RECOMMENDATIONS

The report

Usually the psychiatric evaluator is requested to prepare a report. The APA guidelines (1982) reminded that the content is not confidential and may be used as evidence in court. The report should clearly answer the basic questions addressed in the custody case, including description of the reciprocal attachment between parent and child, the child's needs and the adults' parenting capacities, and the relevant family dynamics. The evaluator should clearly state a recommendation for custody that the evidence in the report should decidedly support. In those cases where the evaluator finds it impossible to make a firm recommendation, he or she should state this and perhaps explore the advantages and disadvantages of different decisions, although this might be less useful to the court. The report should be free of professional jargon and theoretical discourse, though there may be need to discuss particular psychiatric diagnoses when they apply to an involved party and have an impact on the child.

Custody recommendation

Custody may be parsed into *legal* custody, relating to the rights and obligations to make major life decisions for the child, such as choice of school or medical care, and *physical* custody, relating to the rights of the custodian with whom the child resides. Custody may further be categorized as *primary, joint,* or *sole,* relating to the relative allocation of these rights to each custodian (or amount of time the child resides with the custodian).

When formulating an opinion on custody, it is recommended that joint custody be the first considered disposition. Several authors (Galper 1978; Ilfeld et al. 1982; Luepnitz 1982; Ware 1982) have written about the added benefits joint custody may provide. Wallerstein and Kelly (1980) emphasized the importance of a continuing relationship with both parents in helping children recover from post-divorce trauma. Less post-divorce conflict between parents in many ways is in the best interests of the child. The evaluator can emphasize to parents during the evaluation process that they will be brought together again and again

in the future through their children at birthdays, graduations, confirmations, bar mitzvahs, or later, at similar events with grandchildren. Parents must be agreeable and capable of such negotiation, however, and when one parent significantly undermines the other parent, joint custody may not be in the best interests of the child. Krauss and Sales (2000) cited various studies that report on the exacerbation of adjustment problems for children with high-conflict parents where continued contact between parents was necessitated by joint custody arrangements.

The most common alternative to joint custody is single custody by one parent with visitation rights for the other parent. The evaluator usually considers the best fit between parent and child, but sometimes may be forced to choose the least harmful fit. When custody disputes are between a genetic (sometimes referred to as "biological") parent and a nongenetic parental figure, legal precedent has dictated the genetic parent has the right to custody unless proven unfit, despite research demonstrating that attachment behavior is also "biological." The "best interests" standard allows for questioning of this precedent for genetics, and the evaluator may wish to take advantage of this flexibility when it would benefit the child.

A review of visitation and custody state statutes in *Family Law Quarterly* (2013a) shows that, in some jurisdictions, statutes guide the courts to consider if the party claiming visitation or custody rights is a "psychological parent," stands "in loco parentis," or has an "equitable," "de facto," or "substantial" parental relationship with the child. Some states do not necessarily require a showing that a parent is unfit in order for the court to consider application by another party, whereas other states will tend to favor the "superior rights of natural parent," so that once a natural parent is deemed fit, the "custody is decided" (e.g., *Moore v. Moore* 1989, citing *Kay v. Rowland* 1985). In any case, the forensic psychiatrist must remain informed of all relevant statutes, in order to best apply data from the evaluation to the local standards, consistent with the four-step conceptual framework for forensic psychiatric practice advanced in this textbook.

Custody decisions can become more complicated in disputes between the state and a parent where allegations of abuse or neglect exist, given conflict between parents' rights and the state's responsibility to protect the child. The APA (1982) has cautioned custody evaluators involved in such cases to keep focus on the child's rights and needs, as opposed to addressing possible termination of parental rights.

Reynolds et al. (2007) discussed the "approximation rule" to resolve custody disputes (advanced by the American Law Institute in *Principles of the Law of Family Dissolution: Analysis and Recommendations*, 2002), by which judges allocate custody rights based on the approximate amount of time each parent spent taking care of the children before the divorce, as a concrete alternative to the indeterminate "best interests" standard. Obvious criticism is that this alternative standard is overly concrete, unfairly penalizes a breadwinner parent who had less contact with a child due to work obligations, and fundamentally favors an historical parenting arrangement without regard for whether this is in the best interests of the child.

Potential pitfalls

When making recommendations, evaluators need to be consciously aware of personal biases and remember that parents' characters, behaviors, and lifestyles are theoretically relevant only insofar as they affect the child. There is no empirical evidence that parental values affect post-divorce child adjustment, and evaluating parenting values or fundamental religious beliefs may represent an intrusion into constitutionally protected freedoms (Krauss and Sales 2000). Nevertheless, a few states have child custody laws that include consideration of the parents' "moral character" (Emery et al. 2005). The evaluator needs to choose the best or least disadvantageous custody option existing at the time of the evaluation, rather than focus on future possibilities. The evaluator should also try to be clinically flexible regarding alternative living arrangements for custody, for example, with a single parent, gay parent, or father versus mother. Last, it is possible in certain cases to make custody recommendations after having interviewed only one parent (e.g., when one parent refuses to be interviewed), though this is not ideal. AACAP *Practice Parameters* (2011) and the American Academy of Psychiatry and the Law *Ethics Guidelines for the Practice of Forensic Psychiatry* (1987, rev.1995, rev.2005) suggest, if this situation is unavoidable, being clear as to supporting data and qualifying expert opinions rendered without an interview. It is important to note that guidelines are "generally accepted" but are not intended to be rigid. It is important to note why this present evaluation is at variance and how "bias" was avoided in maintaining the "best interests of the child." A recommendation can be made if one can assume that the other parent is normal, and there is still compelling reason to recommend sole custody to the parent interviewed based on positive evidence from the child and the evaluation. It is also possible sometimes to infer aspects of the nonparticipating parent from the children's descriptions. Particularly with older children, they may be reliable reporters of pathology or destructive parenting in the nonparticipating parent.

Informing the parties involved

After making a recommendation and completing the written report, the evaluator may help to diffuse parental disappointment or anger by holding an interpretative interview with the parents (and possibly the attorneys) where the evaluator reviews the reasons behind the custody recommendation. The evaluator should also explain the recommendation to the child. During the interpretative interview, the evaluator can help the parents understand the reasons for the recommendation and may help them come to a negotiated agreement on custody. Ash and Guyer (1986)

reported that in 71% of the cases, after hearing the evaluator's recommendation, parties either stopped litigation or negotiated an agreement. For example, the party for whom custody is not recommended may concede to this decision in exchange for a concession by the other party in a different area of dispute.

Testifying in court

This is not necessary in most cases. Ash and Guyer (1984, 1986) found evaluators were asked to testify in court in only 4%–5% of the cases. When the evaluator is called to testify in court, he or she should prepare by first discussing the recommendation and how it will be presented in court with the *guardian ad litem* or attorneys. One must prepare for the pressures of cross-examination, avoid being swayed by extraneous information, and attempt to testify only on what is relevant to the child's best interests. The best preparation for court is to have a firm recommendation and evidence that clearly supports that recommendation. Lawyers are trained and educated to manipulate, distort, confuse, and obfuscate on cross-examination. The psychiatrist needs to clarify, document, and be logical.

SPECIAL ISSUES IN CHILD CUSTODY DISPUTES

Joint custody and father custody

Levy (1985b) has advocated that fathers and mothers be considered equally for custody and has questioned whether sexism exists in child custody decision making. Ploscowe et al. (1973) have estimated the mother gains sole custody in 80% of cases, the father in 10%, and joint custody occurs in 10% of cases. Ash and Guyer (1984) cited in a random sample of cases from the local jurisdiction that fathers are granted custody in only 5% of cases. Meyer and Garasky (1993) suggested the figure for paternal custody might be closer to 15% based on survey and census data. Kelly (1994) reviewed that there has been a trend toward joint legal custody, and the most common arrangement in the United States is joint *legal* custody with sole maternal *physical* custody, usually with visitation by the other parent.

In the atmosphere of equal rights protections in the 1970s and 1980s, the provision of joint physical custody became an increasingly popular family court disposition. This shift also sprang from child development research into the importance of children's attachment to their fathers. In 1979, California (which adopted the nation's first "no-fault" divorce law in 1970) enacted the first joint custody statute, to be followed in over 40 states by 1991 (Kelly 1994). Some state laws specify a presumption for joint custody, not simply that it be considered (Derdeyn and Scott 1984). Joint custody has been regarded as a means to reduce the negative impact of divorce on the child, by maintaining the child's contact with both parents. However, AACAP (1997) noted for this arrangement to be successful, it likely requires parents who are psychologically healthy and cooperative. High conflict between divorcing parents, dramatic differences in approaches to discipline, and domestic violence might advise against joint physical custody (Reynolds et al. 2007).

Kelly (1994) noted some feminist groups have responded to the emphasis on joint custody by advancing the concept of a primary caretaker standard. The primary caretaker, usually the mother, spends the most time managing the daily needs of the child. This bears similarity to the "tender years doctrine" and to the "approximation rule" (see above). Kelly wrote that a primary caretaker standard, however, ignores the quality of the parent–child relationship and emotional attachment, in favor of counting childcare hours and concrete behaviors. This clearly does not meet the legally predominant standard of what is purely in the "best interests of the child."

Although it is still not usual, granting sole custody to a father is less uncommon than in the past. Lamb (1997) and Fitzgerald and McCread (1981) have discussed evidence that shows infants are strongly attached to both mother and father by the second half of the first year of life. Levy (1985b) also cited multiple other studies that describe the importance of the father throughout a child's development. An APA resource document on child custody issues indicated that the literature provides some evidence that boys tend to do better in father custody and girls in mother custody, all other factors being equal (Binder 1998).

When conducting a psychiatric evaluation for child custody, it is important to use the same criteria to evaluate men and women when assessing parenting capacities, and to recommend custody to the person who can best meet the child's needs. One should recommend custody to a single male if it is clinically indicated, rather than be moved by a sexist bias to recommend something that would not be in the child's best interests.

Gay and lesbian parents

Binder (1998) estimated that 6 to 14 million children have at least one gay or lesbian parent. Gates (2013) estimated that 37% of lesbian, gay, bisexual, and transgendered (LGBT)-identified adults in the United States have had a child at some point in their lives. In the past, when gay men and lesbian women were involved in child custody cases, they were generally denied custody based solely on their sexual orientation. The past several decades have seen slow changes in the way society (and psychiatry) views gays and lesbians. In 1973, the APA trustees voted to eliminate homosexuality *per se* as a mental disorder. After extensive scientific debate, the members of the APA upheld this decision by referendum in 1974. Since the *Diagnostic and Statistical Manual of Mental Disorders, 3rd edition, revised* (*DSM-III-R*, APA 1987), homosexuality has no longer been classified as a psychiatric disorder of any kind. Also, in *Lawrence v. Texas* (2003), the U.S. Supreme Court made a landmark 6–3 ruling against the sodomy law in Texas and effectively legalized

same-sex sexual activity in the United States. Same-sex marriage is now legal in most states, following successful challenges to the 1996 Defense of Marriage Act, including the U.S. Supreme Court's holding in *United States v. Windsor* (2013). Despite these changes, unfortunately, sexual orientation is still a confounding issue in child custody cases today, and some attorneys may contest custody decisions based solely on this issue.

Hutchens and Kirkpatrick (1985) discuss three stereotypes that have led courts to hesitate to grant child custody to gay parents: that gays are psychologically or sexually maladjusted and not mentally fit to raise children; that children raised by gay men or lesbians will grow up to be gay or have gender identity problems; and that children raised by a gay parent will be stigmatized by the custodial parent's sexual orientation. The authors, however, cited numerous psychiatric and psychological studies that scientifically refute all three of these stereotypes, demonstrating that being raised by a gay parent does not compromise child development, and that gays' and lesbians' psychological functioning and parenting skills are not inferior to those of heterosexuals. Freedman (1971) has proposed that gay men and women may actually have better autonomous ego functioning because they were forced to be more independent minded when growing up.

The 1998 APA resource document prepared by the Subcommittee on Child Custody Issues reviewed the relevant literature (Binder 1998) and found no significant differences in parenting between divorced lesbian and heterosexual mothers, and no identifiable differences in the emotional and intellectual development and peer relationships between their children. Also, children of lesbian and gay parents show no statistical increase in the incidence of homosexuality, and there have been no reported cases of pedophilia committed by gay parents or their partners on their children (dispelling a prejudicial fear expressed by some courts). Farr and Patterson (2013) studied heterosexual, gay, and lesbian parents and their adopted children, and found that the quality of parenting behaviors, not family type, accounted for differences in the children's adjustment outcomes.

Hutchens and Kirkpatrick (1985), as well as others (Sadoff and Billick 1981; Herman 1990b), encourage psychiatrists to evaluate gay and lesbian parents the same as any other parent, in order to best ensure that a child custody decision is based on what is in the child's best interests and is not based on prejudice. The same principles of tolerance, objectivity, and neutrality should also apply when the psychiatric evaluator takes into account the rights and needs of youth who are the subjects of custody disputes, including consideration of parental support of the child to develop into a healthy and autonomous LGBT adult (Hulstein 2012).

The mentally ill parent

When evaluating parents who carry a psychiatric diagnosis, one should be aware that such a diagnosis does not automatically mean incompetence as a custodial parent. Herman (1990b) cited examples of psychotic parents who are either capable or incapable custodians. One first evaluates these parents as to their capacity to meet the best interests of the child. In addition, one needs to evaluate the parent's current psychiatric condition, insight, and compliance with and response to treatment. The psychiatric evaluator's recommendations of appropriate treatment for a parent with mental health issues, irrespective of the ultimate custody decision in court, may in the long run benefit both the parent and the children.

The decision for divorce is potentially a product of psychiatric illness. In one case example encountered by one of our authors (SBB), a mother sought divorce during the course of a psychotic depression, and the 14-year-old son told his mother's lawyer that his mother should be hospitalized rather than be divorced. She was, in fact, hospitalized, improved with treatment, and no divorce occurred.

Herman (1990b) noted that both true and false allegations of psychiatric or substance use disorders are common in child custody disputes. The evaluator always needs to verify these diagnoses and not accept them *a priori*. Also, personality-disordered parents, or even delusional parents, might have motives for custody influenced by their pathology, rather than the best interests of their child. Beaver and colleagues (2014) demonstrated a link between psychopathic character traits and negative parenting quality, an intuitive but not previously studied association.

Grandparents and other third parties

National statistics cite that 7.8 million children live in households headed by grandparents or other relatives, and 2.7 million children (or 3% of all U.S. children) are raised by grandparents or relatives (D.C. Child and Family Services Agency 2016). Although grandparent custody is usually a satisfactory arrangement (Schowalter 2000), the legal standpoint on this has varied

The U.S. Supreme Court, in *Troxel et vir. v. Granville* (2000) ruled unconstitutional a Washington State statute permitting visitation by any nonparental third party "at any time" if a court determines such visitation to be in the best interests of the child, noting the statute violated the Fourteenth Amendment Substantive Due Process liberty rights of a custodial mother, Ms. Granville, to make decisions concerning the care, custody, and control of her daughters. The Court cited precedent in a number of cases, including the landmark case *Parham v. J.R.*, 442 U.S. 584 (1979), where the U.S. Supreme Court held that parents should "retain a substantial, if not dominant, role in the decision [to civilly commit a minor], absent a finding of neglect or abuse." The Court also stated that there is a common law tradition to presume parental fitness and that in the case of Ms. Granville, there were no allegations to the contrary. The Court decried that the Washington statute actually weighed the visitation right of the grandparents as more important than "perhaps the oldest of the fundamental liberty interests recognized by this Court."

However, a review of state statutes pertaining to visitation in *Family Law Quarterly* (2013b) revealed that most states view grandparents as having standing to claim visitation rights, and many states also consider claims by stepparents, parents following termination of parental rights or adoption, or any interested party. The review identified that constitutional challenges to grandparent visitation have been made, so that in some jurisdictions visitation may only be imposed on showing that failing to do so would actually be harmful to the child, and is not merely in the child's "best interests" (e.g., *Burnett v. Burnett* 2011).

Allegations of child sexual abuse

Both true and false allegations of child sexual abuse occur in custody battles. The evaluator must be prepared to assess the validity of such allegations and discuss how they affect custody and visitation recommendations. Although Guyer and Ash (1986) reported an incidence for allegations of child sexual abuse of 33% in 400 court-ordered custody evaluations, a study of 9000 families in custody/visitation disputes by Thoennes and Tjaden (1990) yielded a figure of about 2%, replicated by McIntosh and Prinz (1993) who examined 603 family court cases. Thoennes and Tjaden found a similar incidence of false allegations in custody dispute and noncustodial dispute situations, whereas Green and Schetky (1988) emphasized that false allegations of child sexual abuse more commonly arise in the context of a custody battle. Gardner (1987) stated that the majority of children professing sexual abuse in custody situations are actually brainwashed to believe it, as part of the controversial Parental Alienation Syndrome (PAS). PAS was ultimately not included as a mental disorder in the *DSM-5*, because it has never been shown to be both reliable and valid. However, *DSM-5* contains a subtype of Relational Problem V code (not a mental disorder but a focus of clinical attention), *Child Affected by Parental Relationship Distress* (V61.29), which may be a relevant consideration in some custody disputes; and in some cases, the V code of *Child Psychological Abuse* may apply (American Psychiatric Association 2013).

Benedek and Schetky (1985), with a sample of 18 custody dispute cases, found an incidence of 55% for unfounded allegations. However, studies with larger sample sizes yielded more conservative figures. A survey of general child sexual abuse cases reported to a child abuse agency, found that 6% of allegations could not be substantiated (Goodwin et al. 1978). Jones and McGraw (1987) found that 8% of allegations were false, Thoennes and Pearson (1988) 14%, and McGraw and Smith (1992) 16.5%. Penfold (1995) remarked that some authors believe that child sexual abuse may actually be more frequent in divorce (e.g., the stress of the divorce triggering vulnerabilities in a parent, or ongoing abuse coming to light for the first time). She also wrote that some jurists believe virtually all such allegations in the custody context are false, a ploy on the part of the mother to besmirch the father. Raising an allegation of child sexual abuse (whether true or false) may actually jeopardize the accuser's chances of securing custody. The psychiatric evaluator needs to remain objective, but also aware of the importance of carefully examining the validity of these allegations. False allegations can have a potentially harmful impact on the child.

Green and Schetky (1988) have described how one can evaluate the child in such cases and assess the reliability of the child's disclosure. One must first assess the child's ability to separate reality from fantasy and his or her ability to verbally express and recall past events. Both will be a function of the child's developmental level. In general, according to these authors, false denials by children are relatively common, but false disclosures of sexual abuse by children are relatively rare. False disclosures may be seen in a child who has been "brainwashed" by a vindictive parent who seeks revenge or desires to end all contact between the child and the other parent; when a delusional parent has influenced a child; or, occasionally, when a child gives a false disclosure based on sexual fantasies, rather than reality. A child may also falsely accuse a parent for revenge or retaliation. False disclosures tend to be expressed more readily and without a significant change in affect than are true disclosures. Such children may appear outspoken, nondefensive, and may use adult terms, possibly learned from a coaching parent. True disclosures, however, usually are delayed, conflicted, and slow to be revealed, if revealed at all. They may be stated, retracted, and then restated again. They are usually accompanied by appropriate negative affect. The evaluator also should observe the interactions of the child with each parent. In cases of true allegations the child's behavior is usually more consistently fearful toward the accused parent. A young sexually abused child who does not understand the deviant nature of the molestation, however, may display learned seductive behavior toward the accused parent, rather than display fearful behavior. The evaluation may be further supplemented by play therapy with dolls or drawings, though children without a history of sexual abuse can demonstrate explicit sexual play.

When making recommendations for custody and visitation in cases where one is in doubt about allegations of sexual abuse, it is best to be conservative, yet constructive. The evaluator should be careful not to refuse visitation of any kind automatically, as this is rarely required without the consideration of further treatment.

Intimate-partner violence

In most cases, intimate-partner violence (IPV) will settle the matter of custody against the abusing partner, but the psychiatric evaluator may not be able to differentiate allegations from confirmed cases. Stover (2013) noted the psychiatric evaluator may consider the history, nature, and severity of the IPV, and whether the abusing partner still puts the children's best interests first; recommendations around custody and visitation should strongly take the abuse history into account and err on the side of the children's safety. As IPV may exist in the context of substance use and mental health problems, engagement in treatment by the abusing

partner should be evaluated. Stover (2013) also cautioned that since the parent subjected to IPV may have consequent or exacerbated mental health, psychological trauma, and substance use issues, the psychiatric evaluator should exercise caution to not render a custody opinion against a parent who is struggling with the effects of IPV, and in favor of a potentially abusing partner.

Parental kidnapping

Parental kidnapping, the abduction or withholding of a child by one parent from the other parent, may occur in a variety of contexts related to divorce. Katz (1981) has described parental kidnapping to occur before a divorce is finalized by a parent who fears losing custody, or after divorce by the noncustodial parent, who flees to another state with the child to seek a new custody decision, or simply to hide from the custodial parent. Also, after a divorce is finalized, the custodial parent may disappear with the child in an attempt to deny the noncustodial parent visitation (Back and Buxton 1983). Other motives may include an attempt to protect the child from an abusing parent, a desire to blame and punish the left-behind spouse, a desperate effort to effect a reconciliation, or even paranoid delusions, sociopathy, and other mental disorders on the part of the abducting parent (Johnston et al. 1999).

Goodman (1976) estimated that between 25,000 and 100,000 cases occur annually. Lewis (1978) estimated that 60%–70% of cases occur before custody has been decided and go unreported. A national household survey conducted by Finkelhor et al. (1991) showed that over 350,000 families in 1988 saw one parent take unilateral action to deprive the other parent of contact with the child. About one-half of these cases involved actual concealing of the child or flight from the state or country.

Schetky and Haller (1983) have discussed the traumatic effects that parental kidnapping may have on the child, including difficulty in trusting others, withdrawal, poor peer relations, school problems, regression, anxiety, or depression. Johnston et al. (1999) described several risk factors for abduction cases, namely, allegations of child abuse, narcissistic/sociopathic personality traits, unmarried relationship status, low socioeconomic status and minority ethnic status. The latter two factors may be mediated by the reduced likelihood that these families will have the resources or cultural experience to settle their disputes in a legal forum. The authors proposed the courts need to have policies in place to effect rapid decisions or restrictive measures in high-risk situations.

Due to the potential harm to the child, strict criminal sanctions against parental kidnapping should be imposed. The legal system has been taking steps to try to decrease its occurrence, reflected in the prohibition on parental kidnapping in both United States federal law and the Hague Convention (Haller 1987). The National Conference of Commissioners on Uniform State Laws drafted the Uniform Child Custody Jurisdiction Act (UCCJA) in 1968. It has become law in nearly all states. According to Schetky and Haller (1983), this act has been helpful in reducing the likelihood of a kidnapping parent gaining custody of a child through a new custody decree in a different state. Prior to this act, one state was not obligated to honor a custody decision granted in another state. They have also described the addition of further legislation in the 1980s (e.g., the Parental Kidnapping Prevention Act of 1980), where an increasing number of states have made child kidnapping a felony. Even with implementation of these laws, however, parental kidnapping continues to be a significant problem. The Hague Convention on the Civil Aspects of Child Abduction (1980) governs international child abduction cases, calling for the prompt return of an abducted child to his or her habitual residence, unless it is demonstrated that his or her return would expose the child to grave risk of physical or psychological harm, or otherwise place the child in an intolerable situation.

Relocation

Relocation of the primary custodial parents may prompt a custody dispute and evaluation. The California Supreme Court held *In re Marriage of LaMusga* (2004) that a custodial parent does not have a presumptive legal right to relocate, and a court may re-evaluate a custody agreement if the noncustodial parent is able to show that the custodial parent's relocation will be detrimental to the child. Braver et al. (2003) found that maternal relocation is associated with negative impacts on children's long-term relationship with their fathers and their adjustment to the divorce. The authors suggest that their findings warrant reconsideration of Judith Wallerstein's controversial amicus curiae brief (1995) for *In re the Marriage of Burgess* (1996), which advocated that the best interest of the child is to allow the custodial parent to relocate to preserve the "centrality" of the well-functioning custodial parent–child relationship as paramount to positive adjustment of the child during the post-divorce years. However, Bruch (2005) argues that research supports the contention that it is the quality of relationship rather than quantity of visitation between child and noncustodial parent that is more beneficial to the child's adjustment, and that constraining the custodial parent's relocation may adversely impact the custodial environment (e.g., mothers moving to improve their financial situation). As with the debate about overnight visitation for infants and small children, the forensic psychiatrist is likely to provide the most tailored and objective evaluation by considering the particulars of each case at hand, taking research findings into account but refraining from uniformly imposing on every case his or her dogmatic position on the various professional debates.

Harassment of psychiatric evaluators

Of final note as a special issue that may be encountered which is the harassment of the psychiatric evaluator. The psychiatric evaluator should be warned that attorneys are trained to manipulate, coerce, confuse, intimidate, and

distort as part of the adversarial system of the court. An attorney, if losing in court, may attack the evaluator professionally and personally in a vain attempt to discredit the logical or irrefutable facts of testimony. Some marriage/divorce attorneys may take the adversarial system to new extremes. They may attempt character assassination or other discrediting tactics, ignore the merits of the case, lodge ethical complaints, call regulatory agencies, or harass the evaluator in other ways, in order to persuade the evaluator either to come to a decision that favors their party, or to abandon the case entirely. There have even been instances where an attorney has lied over the phone, pretending to be someone else, in order to try to covertly get information from one of our authors who was involved in a custody battle for one of the attorney's clients. Because of the pressures placed on evaluators, many psychiatrists refuse to perform child custody evaluations, which unfortunately is detrimental to children who need their expertise.

Herman (1990a) pointed out that the psychiatrist also may receive personal threats from parents unhappy with the recommendations of the evaluator. Evaluators may be vindictively reported to state licensure boards or professional ethics boards by angry, hostile parents. Issues surrounding child custody elicit deep emotions within parents. Such feelings in a parent for whom custody is not granted may lead to unwarranted attacks on an evaluator, regardless of how well intentioned or reputable the evaluator may be. The evaluator should also be aware of the possibility even of violence when working with bitter, vengeful, dissatisfied parents. It is remarkable and fortunate that competent child psychiatrists subject themselves to this undeserving abuse, in order to guide and protect children from being further victimized by the divorcing process of their adult parents.

SUMMARY

Conducting a psychiatric evaluation in a child custody dispute is difficult, time consuming, and emotionally draining. The evaluator must do extensive interviews and effectively work with the child, parents, attorneys, and other adults significant to the child. The evaluator must make a recommendation that will have a profound effect on the rest of the child's life, even when there may be no clear-cut best recommendation. When formulating his or her recommendations, the evaluator must strive not to be biased by personal prejudice or the persuasive influence of attorneys. He or she must make a decision that is rooted in the evidence of the evaluation and is based only on what is in the best interests of the child. Throughout this process the evaluator needs to maintain his or her stance as advocate for the child's needs. The evaluation process may be painful for the child, the family, and the psychiatrist. The emotional and psychological rewards, however, are great. The evaluator may help provide the potential for a happy, healthy environment for the development of the child, a foundation for later life.

HISTORICAL AND LEGAL PERSPECTIVES

The basic concepts of "parental rights" and the "interests of the child" have gone through evolutionary changes. Until the nineteenth century, the parental rights issue was relatively simple. Under Roman and early English law, the term "parent" referred to the biological (i.e., genetic) father, and children were treated as property of their parents, namely the father. Because wealth and property were considered an extremely important matter, the rights of inheritance were carefully protected and rigorously addressed in the legal system. This created an extreme imbalance between the rights of the parents and those of their offspring.

The term *parens patriae* had its origin in English Law where the king was considered the father or the parent of the citizens of the land. The U.S. government and its individual States function as a parent when it exercises its power of guardianship over persons with disability, such as minors, incompetents, and the mentally ill. Such power is not exercised by the States unless the person under disability has been deprived, for whatever reason, of nongovernmental protection and support of an adequate degree.

The twentieth century was the beginning of a new interest in delineating rights and the interests of the children over the rights and interests of the father, and of both parents. Child labor laws were enacted in the beginning of the twentieth century to further protect children. *In re Gault* (1967) is a pivotal landmark U.S. Supreme Court case regarding children's rights. The Supreme Court upheld a need for timely and adequately specific written notice, the right to counsel, the right to confrontation and cross-examination, and protection from self-incrimination. The need for a transcript and the right to appeal were not ruled on. The majority opinion written by Justice Fortas traced the long history of differences between juvenile and adult cases and offered juveniles many rights similar to those held by adults.

The social movement of the 1960s, with its emphasis on civil rights, influenced the parent–child law. Children were increasingly viewed as real people with specific rights, and society began to take interest in the well-being of minors; hence, the "best interest of the child" concept evolved. As the sociopolitical atmosphere changed again during the 1980s, various rights continued to be re-examined. The rights of parents and children were not viewed as equal by the law. The U.S. Supreme Court, in a series of cases, noted that the biological relationship, although not the exclusive consideration, is in fact, unique, and often prevailing.

Constitutional law holds that the rights of parents to raise their children in a manner they see fit constitutes "family privacy" (*Lochner v. New York* 1905). This suggests that the law allows great latitude to parental actions or inaction toward their children. However, parental rights are not infinite. In the U.S. Supreme Court case of *Prince v. Commonwealth of Massachusetts* (1944), the court stated, "the state, as *parens patriae*, has a wide range of power for limiting parental freedom and authority in things affecting the child's welfare." In *Roe v. Wade* (1973) the court pointed out that when the state intrudes upon a fundamental protected right (family privacy and parental rights), strict scrutiny must be observed by the court. Such a high level of review is mandated to ensure that fundamental constitutional rights have not been abridged.

Parental rights, as recognized by law, include the basic right to custody of their children unless the parents are proven unfit. Parents have authority to control their children until they reach majority, or are being emancipated. The child has no right to leave the parental home for another, although the law recognizes that parental control decreases with the child's increasing age, especially in later adolescence.

In the issue of discipline, the court gives parents wide latitude in the disciplining of children. The parent has the right, authority, and power to discipline the child, if it is viewed as being for the child's benefit. Corporal punishment is included, while abusive punishment is not. In general, if parental discipline is administered with good intent and there is no physical injury, the law will not intervene; however, if malice or serious physical injury results, the parental rights may have been exceeded (American Jurisprudence 22 §22, 1987).

Parents have the right to send their children to private, parochial, or the school of their choice. However, this is a limited right, because the schools must conform to guidelines and standards established by the state educational boards (*Pierce v. Society of Sisters* 1925). Home-based schooling programs following primary school were allowed in the Amish group, as illustrated in the Supreme Court case (*Wisconsin v. Yoder* 1972). Parents have a limited right to bring up their child in a reasonable religion, though inculcating Satanism and human sacrifice would be unacceptable. Religious practices that may affect a child's compulsory school attendance must be a part of an established religion to be acceptable, rather than a mere philosophy or a secular belief.

Parents have the right to hospitalize their children involuntarily for psychiatric evaluation and treatment. An independent medical authority must concur with the need for hospitalization. In many states, the minor child, however, has the right to a judicial review for involuntary hospitalization (*Parham v. J.R.* 1979). In other areas of medical care, the law gives parents broad discretion with limits. A child may be considered neglected if the parents fail to provide proper and necessary medical care (*In re Green* 1972). One of the prominent issues in this area has been the refusal by Jehovah's Witnesses to allow blood transfusion. All states that have ruled in this matter have ordered the blood transfusion if it has a reasonable likelihood of saving the life of the child. The courts have held that adults have the freedom to exercise full religious beliefs for themselves, but cannot exercise unlimited religious beliefs for their child.

In the *Matter of Faridah W.*, 1992, a New York case, the court declared a 16-year-old female who was born with spina bifida and had a neurogenic bladder to be a medically and emotionally neglected child, because her mother refused to permit her to undergo an enterocystoplasty. The court stated that, "A parent has a non-delegable affirmative duty to provide a child with adequate medical care, which has been determined to be that degree of care exercised by ordinary, prudent, loving parents who are anxious for the well-being of the child." The court further noted that the critical aspects of the parents' failure to obtain medical assistance must be to the extent that the child's mental, medical, or emotional health is adversely affected or in imminent danger of being adversely affected. In this case, the mother allegedly refused to comply with the medical expert's opinion and failed to provide a reasonable alternative to the proposed treatment. She also failed to visit her daughter during most of her lengthy hospitalization.

Parents have a right and the authority to determine their child's social activities and how best to meet their child's physical, emotional, and relationship needs. In parent–child relations, after granting custody to one parent, the other parent usually has the vested right to visitation. The Uniform Marriage and Divorce Act (1991) requires clear and convincing evidence that parental contact seriously endangers the child's physical, mental, or emotional well-being to justify termination of the right to visitation.

In many states, it was formerly assumed that an unmarried father had no claim to parental rights, and their permission, therefore, was not required for third-party adoption of their biological child. The Supreme Court, in the case of *Stanley v. Illinois* (1972), addressed a landmark *due process* case regarding parental rights. It was uncontested that Stanley was an unwed father who was seriously interested in his offspring. He had maintained a relationship, provided support payments, and held himself out as a father. The Illinois state law presumed an unwed father to be an unfit parent *per se*, with no opportunity to rebut the unfit determination. However, Illinois law required notice, hearing, and proof of unfitness before neglect proceedings could lead to termination of parental rights. Stanley had no hearing. The court found that Stanley's private interest involved companionship, care, custody, and management of the children he has "*sired and raised*." The court concluded, "It is cardinal that the custody, care, and nurturance of the child reside first in the parents, whose primary function and freedom include preparation [of the child] for obligations the state can neither supply nor hinder." The court went on to state that the integrity of the family unit was protected by the due process, equal protection, and "the rights retained by the people" clauses of the Constitution (*Griswold v. Connecticut* 1965), and that the law has not refused to recognize family relationships not legitimized by marriage. In *Stanley*, the court stated that while the state has a duty "to protect minor children through a judicial determination of their interest in a neglect proceeding," unwed fathers have a due process and equal protection right to have a hearing on fitness when state law declares a married, divorced, or unmarried mother to be presumed fit. Stanley was given a due process hearing and declared unfit to parent his child for other reasons.

TERMINATION OF PARENTAL RIGHTS (TPR)

The law does not view parenting as indigenous to the person, but rather something with which the family is vested by the state. The state assumes it is the parent's responsibility to understand, implement, and perpetuate the values of society. It assumes that a parent has the innate ability to balance rights and responsibilities, relinquish absolute power for the good of the developing child, and treat progeny in such a manner so as to maximize developmental potential. When a parent abdicates, neglects, or abuses this responsibility, the state engenders the doctrine of *parens patriae* to break into the delicate parent–child relationship, expose it to the legal and psychiatric community, and to ask the court's determination as to the appropriateness of terminating an assumed inalienable right of the individual—namely to parent one's own children (Mnookin 1978).

Out of the cruelty to animal laws and the child labor laws emerged early social legislation protecting children's rights. Then came the concept of "the best interest of the child" (Goldstein et al. 1973). The best interest standard is a well-established principle of law in areas of child custody and

termination of parental rights (American Jurisprudence 2d §974, 1983). The concept of "best interests," however, tends to be vague. Some states have attempted to make the issue of best interest clearer and more specific. The District of Columbia (District of Columbia Code, 1981 §16-2353) has codified that the best interest of a child includes factors that consider the following:

1. The child's need for continuity of care and caretakers, and for timely integration into a stable, permanent home
2. The relationship of the physical, mental, and emotional health of all persons involved to the welfare of the child and his or her needs
3. The quality of the relationship of the child with his or her sibling, caretakers, foster parents, and natural parents
4. Whether a child has been left unclaimed in the hospital 10 days after a medical determination that he could be safely discharged
5. The child's opinion of his or her best interests to the extent he or she is able to express them
6. Evidence of continued drug-related activity in the parental home after interventional services have been provided (Armitage 1994)

In the state of California (California Civil Code 226(a) 1991), the court must consider the age of the child, the bonding or potential to bond with natural parents or the adoptive parents, and the ability of the parents to provide adequate and proper care and guidance to the child.

In the state of Michigan (Child Custody Act 1970), factors relating to determination of best interests in custody cases include

1. The love, affection, and other ties between the child and the parents competing for custody
2. Capacity and disposition of competing parents to give the child love, affection, guidance, and education
3. The capacity to provide necessary or any special medical care or remedial care required for the child
4. Length of time the child has lived in a satisfactorily stable environment
5. Permanence as a family unit of the proposed custodial home
6. The moral fitness of competing parties
7. The mental and physical health of the competing parties
8. Home, community, and school record of the child
9. Reasonable preference of the children if they are of sufficient age

In Connecticut (*In re Bernard Pecor* 1992), the court held that a child's best interest involving termination of parental rights cases must be met by considering

- The timeliness, nature, and extent of services offered by the state to help parents reunify (the presumption being that parental rights are important)
- The terms of any court order or agreement between an agency and the parents, and the extent to which the agreements were complied with
- Feelings or emotional ties between the parent and the child, related to the concept of psychological parent
- Age of the child
- Whether mental or behavioral disorders prevent the parents from changing their conduct, behavior, or circumstances that could be injurious to the child in the foreseeable future
- Whether any governmental agency or party prevented the parent from developing a relationship or that the lack of a relationship was based purely on economic circumstances

Congress determined that Native American parents and children were a special class requiring special protections. Federal law gives deference to the parental rights of Native Americans who are members of a recognized Indian tribe. The Indian Child Welfare Act of 1978 requires a finding by evidence "*beyond a reasonable doubt*" that allowing an Indian child to remain with the parent or parents would be likely to result in serious emotional or physical damage to the child. This law requiring a higher standard of proof was enacted because there was substantial evidence indicating that state social workers and others unfamiliar with Native American tribal child-rearing practices (including leaving the child for prolonged periods with other members of the tribe who are considered as "extended family"), inappropriately recommended termination of parental rights.

Schetky and Slader (1980) believe that the law must consider termination of parental rights as it relates to infringement of the rights of children: (a) the right to the maintenance of a parent–child relationship—that is, the right to have someone to call "parent"; (b) freedom from physical, sexual, or psychological mistreatment; and (c) the right to have "primary emotional needs for continuity, consistency and identity" met by being a part of a family.

Definition of TPR

Termination of parental rights means the adjudication that a child is free from the custody and control of either or both his or her living genetic parents by means of court order that completely severs and extinguishes the parent–child relationship (American Jurisprudence 2 & §34, 1987, pp. 172–173). It has, therefore, a profound and serious finality.

Termination of parental rights is governed by both federal and state statutes. The primary law on the federal level is the Adoption and Safe Families Act of 1997 (ASFA). ASFA amended the Adoption Assistance and Child Welfare Act (AACWA) by setting a strict deadline for implementing placement plans. States must comply with ASFA guidelines in order to receive federal funding, and therefore the federal requirements for ASFA have been adopted by all 50 states.

STANDARDS OF TERMINATION

The U.S. Supreme Court has recognized that "freedom of personal choice in matters of family life is one of the liberties protected by the Due Process Clause of the Fourteenth Amendment" (*Cleveland Bd. of Educ. v. LaFleur* 1974). Constitutional law provides minimal standards that must be met in order to terminate parental rights. In *Santosky v. Kramer* (1982), the U.S. Supreme Court held that before a state can completely and irrevocably sever parental rights, *due process* requires that evidence provided by the state be "*clear and convincing*" to support its allegation for termination (Haynes 2009).

The minimal constitutional standard must be met but can be exceeded by state law. Some states currently require "*beyond reasonable doubt*" standards of proof for termination of parental rights. *Due process* in termination proceedings requires fundamental fairness under the legal and factual circumstances of a case. The U.S. Supreme Court invoked the *Mathews v. Eldridge* (1976) elements as rules applicable to deciding what *due process* requires. These elements are (a) the private interest at stake; (b) the government's interest; and (c) the risk that the procedures used will lead to erroneous decisions.

Legal criteria or grounds for termination of parental rights vary among jurisdictions. However, the grounds/criteria must be supported by competent, relevant, clear, and convincing evidence. Common grounds for termination of parental rights include the following:

1. *Voluntary abandonment*: (NY SSL 384-b). A child is abandoned by his or her parent if such a parent evinces an intent to forego his or her parental rights and obligations as manifested by his or her failure to visit the child and communicate with the child or agency, although able to do so and not prevented or discouraged from doing so by the agency. In the absence of evidence to the contrary, such ability to visit and communicate shall be presumed.
2. *Permanent neglect*: This means a child who is in the care and custody of an authorized agency and whose parent or guardian has failed for a period of more than 1 year (after foster placement) to substantially and continuously or repeatedly and consistently maintain contact with or plan for the future of the child although physically and financially able to do so, notwithstanding the agency's diligent efforts to encourage and strengthen the parental relationship when such efforts will not be detrimental to the best interest of the child. It is important to note that a visit or communication by a parent with the child, which is of such character as to overtly demonstrate a lack of affectionate and concerned parenthood, shall not be deemed a substantial contact.
3. *Mental illness*: This means an affliction with a mental disease or mental condition that is manifested by a disorder or disturbance in behavior thinking, feeling, or judgment to a such an extent that if the child were placed in or returned to the custody of the parent, the child would be in danger of becoming a neglected child.
4. *Mental deficiency*: This means sub-average intellectual functioning, which originates during the developmental period and is associated with the impairment in adaptive behavior to such an extent that if the child were placed or returned to the custody of such parent, the child would be in danger of becoming a neglected child.
5. *Physical/sexual abuse*.
6. *Substance abuse*: When the parental substance abuse leads to danger of neglect or abuse of the child.

When the state interferes with parental rights as in involuntary termination of rights, it must carefully follow legal procedures and substantive law that reflects the grounds and criteria for termination. These procedures can vary among jurisdictions. In most cases, circumstances that take place in a child's life warrant interference by state agencies to take temporary custody of the child, as in cases of neglect, abandonment, or abuse by the parents or legal custodians. The child is initially removed on an emergency basis by a state agency such as child protective services. Hearings on this action are required and there must be substantive evidence of neglect or abuse based on *preponderance of evidence*.

The court then mandates the state agencies to make diligent efforts to assist the parent toward reunification with the child unless reunification is not possible, or is not indicated. All jurisdictions allow for waiver of reunification attempts under certain circumstances. When legal criteria and grounds for termination are met, a termination hearing is ordered following a petition by the state. The grounds for parental unfitness and termination must be stated and must be proved by *clear and convincing evidence.* The next procedural requirement is to prove that termination is in the best interest of the child by *clear and convincing evidence.*

Testimony of a child psychiatrist is frequently used in termination of parental rights cases. In addition to the prominently accepted principle of the "best interest of the child," the concept of "least detrimental alternative" has been applied in some cases.

STATISTICS OF TPR IN THE UNITED STATES

The U.S. Department of Health and Human Services, Administration for Children and Families publishes *Trends in Foster Care and Adoption*. The most recent publication in 2014 describes data from 2002 to 2013. During this time, there was a range of Parental Rights Terminated from 59,000 in 2013 to 82,000 in 2007.

CLINICAL ISSUES RELATED TO TPR

All clinical issues and evaluation must be viewed within the context of the legal grounds and criteria for termination.

MENTAL DISORDERS AND MENTAL ILLNESSES

Psychiatrists and psychologists are called to provide evidence in TPR proceedings when mental illness or deficiency is a proffered ground for termination. In New York, a parent's right can be terminated on the grounds of mental illness if the suffering parent is rendered incapable of caring

for the children. The state is not required to make efforts to strengthen the parental relationship, and it is not required to show that efforts to strengthen the parental relationship would be detrimental to the child (*In re Demetrius F.* et al. 1991).

All clinical evaluations must be viewed within the context of the legal grounds for termination. Involuntary hospitalization for the mental disorders, combined with other factors that are offered as evidence that the hospitalized parent may be dangerous to the child, is a frequently recognized ground. A diagnosis of schizophrenia *per se* may not be accepted as evidence for unfitness. The schizophrenia must have an adverse impact on the ability to parent by interfering with the individual's thinking, perception, behavior, and judgment. Other associated problems such as poor or noncompliance with medication and recommended treatment, refusal to participate in parenting skills training and erratic parent–child interaction during visitation are also important areas of assessment.

A borderline personality disorder has been accepted as a diagnosis of "mental illness or disorder" and deemed by the court to be a long-term condition allowing for termination, if termination is in the best interest of the child, because such a parent was not considered capable of performing proper parental duties. The same parent did not comply with a court-ordered rehabilitation plan for reunification, which the court held as an independent reason, in addition to the mental disorder, to terminate parental rights (*In re the Interest of B.M. v. L.M.* 1991).

PARENTAL INCARCERATION

Criminal incarceration of a parent as a factor in TPR varies among jurisdictions. Parental incarceration is a growing problem that needs accommodation in the current time-driven model of permanency planning. Child welfare agencies need to recognize the importance of maintaining parent–child relationships, even when a parent is incarcerated, and to develop creative approaches for dealing with the unique challenges of parental incarceration.

Over the past 15 years, the population of female prisoners has increased by almost 400%, while the male prison population has increased by more than 200% (U.S. Department of Justice 1995). Two-thirds of the female prisoners in the United States had one or more children under the age of 18 years. In 1991, 72% of incarcerated mothers had minor children who had lived with them before entering prison. Approximately 50% of the incarcerated fathers had lived with their children prior to imprisonment (Snell 1994). In the survey of 1991, 71% of the children of incarcerated mothers and 13% of the children of incarcerated fathers were with grandparents or other nonparent relatives (Snell 1994). These data show that incarcerated mothers must rely on nonparent caregivers for childcare to a much greater extent than incarcerated fathers. Some 90% of the children of incarcerated fathers were cared for by their mothers (Johnston 1995), but only 25% of the children of incarcerated mothers were cared for by their fathers (Snell 1994).

Parental imprisonment does not change the basic legal requirement governing permanency planning. Agencies have a legal obligation to make "reasonable efforts" to preserve and strengthen the relationship between incarcerated parents and their children. The definition of reasonable efforts varies from jurisdiction to jurisdiction. For example, New York state law defines diligent efforts to incarcerated parents as including "making suitable arrangements with a correctional facility and other appropriate persons for an incarcerated parent to visit the child within the correctional facility, if such visiting is in the best interest of the child. … Such arrangements shall include, but shall not be limited to the transportation of the child to the correctional facility, providing social or rehabilitative service to resolve service to resolve or rectify problems which can impair the incarcerated parent's ability to maintain contact with the child other than incarceration itself" (NY SSL 384-b(7)(f)(5)). The most obvious challenge to the agency is the facilitation of a continued parent–child relationship relating to lengths of sentencing and distance.

The length of sentencing is likely to increase in the future as legislative efforts to eliminate or seriously limit parole result in more time served. At the same time, mandatory sentencing laws for certain crimes will lead to the imprisonment of even more parents. Distance is the other problematic issue affecting the ability of agencies to provide services to an incarcerated parent. Women's prisons are often located in rural areas, and inaccessible by public transportation. Despite these obstacles, the agencies must generally attempt to overcome them and assist the parent and child to maintain a meaningful relationship. Parental rights are not absolute, and in inappropriate cases, where diligent efforts are not in the best interest of the child, the state may go to court to seek TPR. To do so, the state must prove the parent is "unfit" (*Stanley v. Illinois* 1971; *Santosky v. Kramer* 1982).

The parent's "fitness" must be measured by the parent's ability to "maintain a place of importance in the child's life" (*In re Adoption of Sabrina* 1984). Recognizing the principle that parental incarceration does not automatically amount to unfitness, New Jersey's Supreme Court has articulated the factors that must be examined in TPR evaluations of incarcerated parents:

1. Parent's performance before incarceration
2. The extent to which children were able to rely on their parent
3. Parent's efforts to remain in contact with the children since incarceration
4. Parent's ability to communicate and visit with their children
5. The effect of parental communication and visitation on the children
6. The ability to provide nurturance and emotional support to their children
7. Risks posed to the children by the parent's criminal actions
8. The extent of the parent's rehabilitation during incarceration

9. The need of the children for permanency and stability and whether continuation of the parent–child relationships will undermine that need
10. The effect that the continuation of the parent–child relationship will have on the psychological and emotional well-being of the children

The trend toward incarceration of greater numbers of people for longer periods of time shows no signs of abating. As a result, increasing numbers of out-of-home caseloads will involve children of incarcerated parents. Effective family work in cases involving parental incarceration requires significant expenditure of time and resources. The child protective agencies should identify the cases where efforts would be successful in maintaining and strengthening viable parent–child relationships. In such cases, agencies must develop new permanency approaches, consistent with the requirements of the Adoption and Safe Families Act (ASFA 1997), for families in which a parent is incarcerated. For many children of incarcerated parents, the best permanency plan is one in which the parent continues to play a significant role in the child's life (Genty 1998).

CLINICAL ISSUES AND THE ROLE OF CHILD PSYCHIATRIST IN TPR EVALUATION

As numerous studies have documented, many children languish in foster care with little or no efforts being made to make permanent plans for them, in spite of the fact that their biological parents may be failing to progress toward the goal of reintegrating them into the family. Although foster care is thought of as a temporary placement, studies have shown that once a child is in placement, he or she has a 50% chance of remaining there for 3 years or longer (Wald 1976).

In terms of assessing the child's needs in this situation, there appears to be few clear-cut guidelines, and the available studies usually either relate to divorce (Malmquist 1968; Benedek 1972; Derdeyn 1976, 1978) or concentrate on legal aspects of such decisions (Foster and Freed 1964). Goldstein et al. (1973) introduced the concept of "psychological parent," and urged the court to make decisions based on the children's needs, interests, and the time perspectives. Schetky et al. (1979) directed their study toward a broader group of parents who failed to meet their children's needs and also had their parental rights terminated by the court. Their study of 51 parents whose rights were terminated revealed that the TPR cases were primarily cases of neglect rather than abuse. Most deal with abandonment or neglect. Less than 10% of all court cases involve physical abuse. In most cases, parents' backgrounds were notable for severe social, economic, and educational disadvantages, leading to family disruptions, problems with parent–child relationships, and out-of-home placements. Many were victims of neglect, physical, and sexual abuse. These parents were marginally functioning with interpersonal difficulties, unstable marriages, social mobility and isolation, and difficulty finding employment.

Many displayed low self-esteem, impulsivity, poor judgment, and difficulty planning ahead. The parents had serious deficiency in the capacity for empathy and an inability to put their children's needs before their own. They viewed their children as existing to satisfy their needs. Parents were deficient in their own role models for parents and had impaired object relations. Emotional illness in mothers often contributed to the neglect of the child. Mental illness in mothers was frequent: some 40% of mothers had psychiatric illnesses, were hospitalized for treatment, or sought outpatient treatment at some point. Fathers were notable for the absence of psychosis, but presence of *serious* personality disorders, antisocial personality disorder (ASPD) being most frequent. Neglectful parents are harder to reach and help than abusive parents. One possible reason is the fact that neglect is more insidious and more difficult to detect. A study of children languishing in foster care showed that many were experiencing developmental delays, had symptomatic behaviors, problems in response to visitation, and delays in academic performance.

In spite of the above findings, many children were doing well in long-term foster care and eventual adoptive homes. At the time of termination, all children had formed positive attachments to foster parents. It is important to stress that age, mixed race, presence of minor behavior problems, and duration of time in foster care were not barriers to finding adoptive homes for these children.

Fanschel (1976) noted that psychiatrists, in their evaluation of parents and children, and all parties pertinent to the case, should search for (a) covert aggression; (b) role reversal where the child has inappropriately become the parent of the parent, or is serving so many psychological needs of the parent that it amounts to serving in a parental role; (c) indications that the child is being drawn into the marital dysfunction; and (d) the existence of age-inappropriate expectations of the child often combined with little appreciation of the child's own feelings and needs as separate from the parents, or lack of knowledge of developmental norms. In addition to a variety of factors considered in light of the legal criteria, clinical issues such as the severity and duration of the parent's abnormal mental or emotional condition or conduct must be evaluated.

The likelihood of the parents changing their abnormalities, allowing reintegration of the child into the home within a reasonable period of time consistent with the current ASFA requirements, must be addressed. The issue of whom the child truly views as his or her parent—that is, who is the psychological parent of the child—must be assessed. Finally, the psychiatrist should also consider options for placement of the child and the "*least detrimental alternative*" when making a recommendation, bearing in mind the problems of children in prolonged foster placements.

Although the "best interest of the child" is a universally applied principle in most jurisdictions, the concept of "psychological parent" and the "least detrimental alternative" has also been heavily relied on as important in many jurisdictions.

CLINICAL CRITERIA FOR TPR

The information in this kind of evaluation must be weighed for and against termination of parental rights with a precision that exceeds the legal criteria, for the legal criteria in themselves are not very specific and not well defined to make an easy recommendation:

1. Basic aspects of the evaluation should include examination of the child individually, with both biological parents and foster parents. All participants should be informed of the limits of confidentiality or lack of confidentiality in the evaluation.
2. Review of all records from ancillary sources such as child's school, medical records, psychiatric treatment, child protective service, or agency records should be carried out to obtain history and factual information.
3. A thorough evaluation of the child's stated parental preference must be explored in the context of a child psychiatric evaluation.
4. The child's perception of the parent's abuse, neglect, and unavailability should be assessed.
5. Evaluation must be made of the child's development, including medical examinations, developmental milestones, and psychological testing.
6. Assessment should be made of parental attitudes, knowledge of parenting skills, and the parents' own development and emotional maturity (development).
7. Determination should be made of how parents coped with stressors/demands during their child's development.
8. Evaluation of the parents' perspective as to their own difficulties and alleged reasons for termination of parental rights should be conducted.
9. Psychiatric mental status examination of all parents should be conducted to assess psychopathology.
10. Assessment of child–parent interaction in an unstructured play setting is useful in detecting covert hostility, anger, and detachment.

Additional criteria or guidelines include the following:

1. The parental availability to provide continuity and consistency of care.
2. Parental empathy and their ability to recognize the child's needs as different from their own.
3. Parental affection, warmth, and nurturance toward their children. It may be helpful to explore the parent's own history of nurturance during his or her development if relevant, as many neglectful parents have a history of having been neglected or deprived themselves.
4. Parents' intelligence in terms of their ability to manage daily practical affairs in their own lives and its effects on their parenting availability.
5. Parental ability to utilize help from professional and personal supports, as well as community supports.
6. Parents' ability to successfully rehabilitate. Has there been parental improvement enough to keep pace with the child's developmental needs? Is the parent able to apply her or his knowledge of parenting skills to the child?
7. What special needs does the child have? Have they been met in order to foster satisfactory development?
8. The quality and intensity of the child's attachment to the natural parents as well as surrogate parents.
9. The parental ability to set limits with the child to help the child develop internal controls and effectively interact with her or his environment.
10. Long-term or permanent availability of surrogate parents as well as the adoptability of the child.
11. Evaluation of the parental separations or absences with appropriate comments on their implication on the child.
12. The parent's inability to take care of himself or herself either when the child was at home or placed out of the home.
13. The limitations of psychiatric treatment with certain psychiatric disorders (e.g., personality disorders, organic brain syndromes, severe developmental disorders).
14. The parent's refusal to use treatment that could be beneficial.
15. The gains made by children while living in foster care.

In summary, this comprehensive approach to evaluation involves a progression from assessment of the parental conduct or condition, to the parent–child relationship, to the effects of the parent's conduct on the child, to the child's relationship with the surrogate parent, and finally, the child's needs. This may also satisfy the court's need to protect parental rights and focus on parental fault in terms of the effects on the child and his or her development (Schetky et al. 1979).

Ethical issues and expert testimony in forensic child psychiatry

Termination of parental rights evaluation is a sensitive issue, and it is at this delicate interface of societal values, parental rights, and children's rights that the psychiatrist is asked to render an expert opinion.

The role of a psychiatrist in such evaluations is to assume the position of evaluating appropriate parenting skills and behavior rather than to make pure diagnostic and clinical statements. Weighing competing interest poses an ethical dilemma even when guided by the universally applied principle "best interest of the child." There is a terrible finality to termination of parental rights. Common ethical dilemmas that can potentially arise in TPR evaluations include

- Will the parent improve with giving him or her one more chance?
- How does termination affect the parent's mental health?
- Are there educational and social class biases that may affect our recommendations?

- How do we balance the interest of the child who is thriving well in foster care with the concern for the child's impoverished mother who has shown minimal improvement?

Therefore, a psychiatrist's participation in TPR evaluations runs headlong into the basic value system fundamentally ingrained in the teachings of psychiatry—namely professional neutrality, clinical tolerance to a wide range of lifestyles, the family's right to privacy, dependent decision making, and the belief that intact family is the cornerstone of our social, emotional, and developmental matrix. Finally, the ultimate decision of termination presents not only the parents' personal failure in adequately providing for their children, but also the failure of society's ability to rectify through all means, including psychiatric intervention, the basic flawed parenting styles that brought the family to professional attention in the first place. It is imperative that the courts understand the limit of our current expertise in defining appropriate or adequate parenting skills and our limits in facilitating these virtuous qualities in parents who are grossly inadequate or negligent in assuming parental responsibility (Schoettle 1984).

Psychiatrist's testimony on clinical issues of TPR evaluations should also include history of parental absences and separations from their child, the parent's failure to rehabilitate or change, even with professional assistance, and their inability to utilize help in planning for the return of their children. Limitations of psychiatric treatment for several diagnostic categories such as organic brain syndrome, mental retardation, and severe personality disorders must be acknowledged. It is important to document evidence that the child has made clear developmental gains while in foster care and/or any reversal of developmental delays or abnormalities which the child previously revealed while under the parent's care and custody.

PERMANENCY AND ADOPTION: FEDERAL REGULATIONS AND LEGAL PERSPECTIVES

Definition of adoption

The Child Welfare League of America defines adoption as the method provided by law to establish the legal relationship of the parent and child between persons who are not related by birth. Adoption is the legal proceeding whereby an adult person takes another adult or minor person into the relation of child and thereby acquires the rights and incurs the responsibilities of parent with respect to said adult or minor (Section 110 of the N.Y. Domestic Relations Law).

Statistics of adoption in the United States

It has been estimated that about two million children in the United States are adopted; this amounts to about 2% of all children in the United States (Kreider and Lofquist 2014).

1. One-quarter of these children were adopted by relatives (National Survey of Adoptive Parents 2007).
2. Of the children adopted, and not including step-parent adoptions,
   a. 37% were adopted from foster care.
   b. 38% were adopted through private domestic adoptions.
   c. 25% were adopted internationally (National Survey of Adoptive Parents 2007).

There are about four million stepchildren in the United States; this amounts to nearly 5% of all children in the United States (Kreider and Lofquist 2014). The exact number of adoptions occurring annually is unknown because there is no authority collecting this data.

The U.S. Department of Health and Human Services, Administration for Children and Families publishes *Trends in Foster Care and Adoption*. The most recent publication in 2014 describes data from 2002 to 2013. In 2013, there were 51,000 children adopted in the United States; there were 102,000 children waiting for adoption in the United States. The number of children awaiting adoption has been relatively stable during the period of 2002–2013; more specifically there have been between 50,000 and 57,000 adopted during this time. The number of children awaiting adoption has decreased from about 130,000 from 2002 to 2007 to closer to 100,000 from 2011 to 2013.

Legal aspects of adoption

Children are adopted through several different means. The most common method of adoption occurs through state foster care agencies, which are legal in all states. There are also licensed foster care agencies, licensed private adoption agencies, private independent adoption agents (facilitators), and the U.S. Department of State. In April 2008, the U.S. Department of State became the controlling representative of the United States to the Hague Convention of 1993 on Protection of Children and Co-operation in Respect of Intercountry Adoption, which then activated the U.S. Intercountry Adoption Act of 2000 (Public Law 106-287). In brief, the 1993 Hague Convention created safeguards to ensure that intercountry adoptions were in the best interest of the child and with respect to his or her fundamental rights (Hague Convention 1993).

Adoption can be "closed," with virtually no contact between biological and adoptive parents; or "open," with varying degrees of contact between parties. The court has power under the N.Y. Domestic Relations Law, Section 111, not only to grant an adoption but also to grant the natural parents visitation rights even after the adoption, if it is in the best interest of the child. This is referred to as an *open adoption*.

Adoptions today are not restricted to two-parent heterosexual couples. Single-parent and other nontraditional family structures such as homosexual couples also adopt children. Regardless of the route or type, the adopted child

has the same legal status with respect to his or her adoptive parents, as do any biological children. Once adoption is final, the biological parents no longer possess legal rights to the child. However, statutory laws may vary on the timing and specifics of these legal issues.

Adoption through foster care

BILL OF RIGHTS FOR FOSTER CHILDREN

Ratified in Congress Hall, Philadelphia, on April 28, 1973, this is composed of the following points:

- *Even* more than for other children, society has a responsibility along with parents for the well-being of foster children. Citizens are responsible for acting to insure their welfare.
- *Every* foster child is endowed with the rights inherently belonging to all children. In addition, because of the temporary or permanent separation from and loss of parents and other family members, the foster child requires special safeguards, resources, and care.

Every foster child has the inherent right:

- *Article of the first*: To be cherished by a family of his or her own, either the child's family helped by readily available services and supports to reassume his or her care, or an adoption family, or by plan a continuing foster family.
- *Article of the second*: To be nurtured by foster parents who have been selected to meet his or her individual needs and who are provided services and supports, including specialized education, so that they can grow in their ability to enable the child to reach his or her potential.
- *Article of the third*: To receive sensitive, continuing help in understanding and accepting the reasons for his or her own family's inability to take care of him or her, and in developing confidence in his or her own self-worth.
- *Article of the fourth*: To receive continuing loving care and respect as a unique human being…a child growing in trust in himself or herself and others.
- *Article of the fifth*: To grow up in freedom and dignity in a neighborhood of people who accept him or her with understanding, respect, and friendship.
- *Article of the sixth*: To receive help in overcoming deprivation or whatever distortion in the child's emotional, physical, intellectual, social, and spiritual growth may have resulted from his or her early experiences.
- *Article of the seventh*: To receive education, training, and career guidance to prepare him or her for a useful and satisfying life.
- *Article of the eighth*: To receive preparation for citizenship and parenthood through interaction with foster parents and other adults who are consistent role models.
- *Article of the ninth*: To be represented by an attorney-at-law in administrative or judicial proceedings with access to fair hearings and court review of decisions, so that the child's best interests are safeguarded.
- *Article of the tenth*: To receive a high quality of child welfare services, including involvement of the natural parents and his or her own involvement in major decisions that affect his or her life.

June 20, 1972, was an important day for the foster child in New York State. It was the first day that a Section 392 foster care review hearing was held at family court, New York County, with Judge Edith Miller presiding. Prior to the enactment of Section 392 of the social service law, there was no court review of the thousands of children in foster care. It was thought that because of lack of court review many children in foster care remained in foster care needlessly and many more should have been adopted, while others should have returned home to their natural parents.

Section 392 of the SSL mandates that once a child has been in foster care for a continuous period of 18 months, the authorized agency charged with the care of the child must file a petition in family court seeking review of the child's status. The petition must set forth the disposition sought (that is, return of the child to his or her natural parents, continuing foster care, or initiating the proceedings to free the child for adoption), and the grounds or reasons for such disposition. All interested parties such as the authorized agency, the natural parents, and the foster parents are given notice by mail of the hearing. The court has the power to direct the agency to undertake diligent effort to encourage and strengthen the parent–child relationship when it finds such efforts will not be detrimental to the best interest of the child. Finally, the family court that has continuing jurisdiction may rehear the matter when it is deemed necessary but within 24 months (as in *Matter of Sheila G* [61 N.Y.S 2d 368, 474 N.Y.S 2d 421]). The family court is vested with continuing jurisdiction over the child until there has been a final disposition of custody. After the child is returned to the natural parent by the Social Service agency the family court loses its jurisdiction (as in *Matter of Lucinda G* [122 MISC 2d 416, N.Y.S 2d 736 (1983)]).

International adoption

The adoption of children born abroad began mainly after World War II when orphaned European children were adopted by U.S. parents (Alstein and Simon 1991). In the 1950s, after the Korean War, international adoption became more prevalent, especially children from Korea (Alstein and Simon 1991). In the late 1970s, adoption within the United States increased. In the 1990s, international adoption increased from Eastern Europe and China. The highest number of international adoptions occurred in 2004 when it is estimated that globally 45,000 children were adopted, 23,000 of those to parents in the United States. In 2008, the Intercountry Adoption Act (IAA) required that adoption agencies be accredited (Bailey 2009).

The overall decrease in international adoption is shown in the decline in immigrant visas issued to orphans coming

to the United States for adoption. The number of adopted children coming to the United States decreased from 18,000 in 2000 to 11,000 in 2010 (Selman 2012a,b). In 2009–2011, about half (51%) of the internationally adopted children were born in Asia, one-fifth were born in Latin America, and one-quarter (25%) were born in Europe (U.S. Census Bureau, American Community Survey 2012). Of the adopted children from Asia, 57% were from China and 23% were from Korea; this is in contrast to before the 1990s when 71% of adopted children were from Korea (Selman 2012a,b). The majority of children adopted from Europe (73%) were from Russia and the majority of children adopted from Latin America (71%) were from Guatemala (Selman 2012a,b).

Transracial adoption

Based on the 2007 National Survey of Adoptive Parents, 40% of adopted children (not including those adopted by step-parents) were involved in a transracial, transethical, or transcultural adoption (Vandivere et al. 2009). In the past, transracial adoption has been opposed and restricted. The Multiethnic Placement Act of 1994 sought to eliminate these barriers. More specifically, the goals of this act were to decrease the length of time that children wait to be adopted, facilitate identification and recruitment of families that can meet the child's needs, and prevent discrimination based on race, color, or national origin (Multiethnic Placement Act 1994).

Historians of transracial placement in the United States generally agree that its occurrence, similar to international adoption, was extremely rare up to World War II (Silverman and Fiegelman 1990; Simon 1994). Initially, it occurred on a moderately large scale as a form of intercountry adoption from the 1960s to the mid-1970s. First, U.S. military involvement in the Far East was the background to the adoption of Japanese, Chinese, and subsequently Korean and Vietnamese children by Caucasian Americans. The adoption of Hispanic children from Latin America has also been considerable (Feigelman and Silverman 1983). Second, liberal child welfare regulations actively promoted transracial placement as a means of assisting disadvantaged African–American children by finding alternatives to institutionalization. Third, Caucasian families were willing to accept placement of African–American children and were then seen as progressive in being prepared to withstand stigma for the sake of principle, as many were motivated by the ideal of a more racially integrated society.

However, opposition arose against transracial placement. Concerns in both Native and African–American communities were based on the view that their culture was threatened with depletion if their children were placed away from home into Caucasian families. The rise of the civil rights and African–American consciousness movements took child welfare practice into the political arena, and the increasingly confident voice of some African–American professionals was raised in criticism of the adoption establishment. Transracial placement became emblematic of wider historical and political injustices. Such views were understandable in light of the lack of prior involvement and consultation with the African–American professionals and their community about the placement of African–American children in care. Hence, there followed a sharp decline in such placements after 1976.

Some reviewers have disputed that this opposition was justified and maintain that "transracial placement" is a viable means of providing stable homes for waiting children. Identity is one of the concepts most used by anti-transracialists. It is crucial to child development, but its meaning remains less resolved. Some authors present "a positive sense of racial identity" as a unified achievable goal (Maximé 1986), whereas others stress its fluidity and context dependency (Katz 1995). It has been defined as having overlapping parts such as personal identification and feelings about the self, as well as the degree of identification with various social groupings (Richards 1994). The process of transracial adoption seems to produce children whose self-esteem is at least as high as that of nonadopted children, and whose adjustment appears to be more than satisfactory (Silverman and Feigelman 1990, 199).

In 2009–2011, there were 438,000 transracially adopted children under the age of 18, which is 28% of all adopted children under 18. Compared to other children, transracially adopted children tended to be younger (Kreider and Lofquist 2014). A higher percentage of transracially adopted children lived with married parents, specifically 77% compared to 71% of other adopted children. Transracially adopted children lived in households with higher income, lower poverty rates, and with a higher percentage of advance education compared to children adopted by the same race of parent (Kreider and Lofquist 2014). These statistics make sense given the higher proportion of these children who are also internationally adopted (Child Welfare Information Gateway 2011; Ishizawa and Kubo 2014).

THE ADOPTION AND SAFE FAMILIES ACT (ASFA) OF 1997

The ASFA of 1997 amended the 1980 Adoption Assistance and Child Welfare Act (P.L.96-272), the federal statute that provided for partial federal reimbursement to states for child welfare and out-of-home care expenses (Adoption and Safe Families Act, Public Law 105-89). To qualify for reimbursement, state child welfare and out-of-home care plans must comply with the requirements of the 1980 statute, as amended by ASFA.

In the provisions of the 1980 act was the requirement that state child welfare agencies make reasonable effort to preserve families by avoiding unnecessary out-of-home care placements and, where out-of-home care placements could not be avoided, by reunifying families as quickly as possible. ASFA modifies this "reasonable efforts" requirement in some respects. First, the statute establishes "health and safety of the child" as the most important consideration in determining what family preservation and reunification efforts are required.

ASFA also sets forth three exceptions to the reasonable efforts requirement:

1. If the agency alleges that there are "aggravated circumstances" defined as severe or repeated child abuse, which may include abandonment, torture, or physical and sexual abuse
2. If the parent has been convicted of murder or manslaughter of a sibling or half-sibling of the child, or a felony assault resulting in serious physical injury to the child or another child of the parent
3. If the parental rights of the parent to a sibling have been terminated involuntarily via termination of parental rights proceeding, as opposed to a voluntary surrender (ASFA §101(a)(15)(D))

In addition to modifying the reasonable efforts requirement, ASFA also imposes new requirements for expedited filing of termination of the parental rights proceeding. The statute requires a state to file a petition for termination of parental rights for all children who have been in foster care for *15 of the most recent 22 months*, including all children already in care.

The TPR petition is to be immediately filed for children for whom "aggravated circumstances" (e.g., severe or repeated child abuse) has been found or whose parent or guardian has an enumerated serious criminal conviction (*Santosky v. Kramer* 1982, at 455).

U.S. 745 (1982) requires a higher burden of proof in a termination based on repeated abuse. The statute provides exceptions to the requirement to file termination of parental rights petition where

- The child is in kinship care.
- The agency documents "compelling reasons" which may include (a) a lack of sufficient grounds for a petition to terminate parental right; (b) inappropriateness because the child is in placement as a juvenile delinquent or person in need of supervision (PINS); (c) has a permanency goal other than adoption; and/or (d) refusal of a child over the age of 14 years to consent to adoption.
- The agency has not provided reasonable efforts to reunify the family, although legally required to do so.

The other significant amendments include criminal background checks for prospective foster and adoptive parents (42 USC 671(a)(20)(A)). The federal statute further provides that a prospective foster or adoptive parent must be denied placement of a child if the background check reveals

- A felony conviction at any time for child abuse or neglect, spousal abuse, or violent crimes, including homicide, sexual assault, or rape
- A felony conviction within the past 5 years for assault, battery, or a drug-related offense

The federal act additionally provides that the state must hold an initial permanency hearing for foster children within 12 months of the date the child entered foster care (42 USC 675(5)(c)). The date the child entered foster care is defined as the 60 days after the child was removed from his or her home. At this permanency hearing, the court determines the appropriateness of the child's permanency plan, including whether and when the child should be returned to the parent, placed for adoption, referred for legal guardianship, or placed in another planned permanent living arrangement.

These amendments were made to expeditiously transition foster-care children into suitable permanent homes. It was felt that foster care should serve mainly as a temporary safe haven for children—a secure setting where they can live while suitable permanent homes are being located for them.

The Adoption 2002 Report, a federal government undertaking in response to President Clinton's initiative on adoption and foster care, has outlined several important assumptions in its memorandum, including

1. Every child deserves a safe and permanent family.
2. Children's safety and health are of paramount concern and must guide all child welfare services.
3. Children deserve prompt and timely decision making as to who their permanent caregivers will be.
4. Permanency planning begins when a child enters foster care.
5. Adoptive families require support after the child's adoption is legalized.
6. The diversity and strengths of all communities must be tapped.
7. Quality services must be provided as soon as possible to enable families in crisis to address problems.

PERMANENCY AND ADOPTION: AN OVERVIEW

Family preservation beyond the best interest of the child

Family preservation should not compromise the well-being of children. When parents cannot be rehabilitated, or when parents' problems are too complex to be resolved in the short term, children bounce between the biological family and foster care, drifting from foster home to foster home. In such cases, the best interests of the children are not served.

The current foster-care system is overburdened, and the number of available, qualified foster parents has steadily diminished since the 1980s. This diminution is partly due to the increased needs of children traumatized by poverty, physical and sexual abuse, drug and alcohol exposure, and emotional maltreatment at the hands of both parents. Because traditional foster care was not designed to meet these special needs, specialized and therapeutic foster-care homes have become available. For many children, foster care remains a viable option for reducing risk. Kinship

foster care also works in the interests of family preservation by allowing a relative to become a foster parent. The federal government has funded several projects to examine the practice elements in kinship adoptions. Evidence available suggests that the likelihood of kinship adoption of foster children depends, in great part, on the ethnicity of the children. Evidence also suggests that kinship adoptive families look vastly different than other adoptive families and are poorer, less educated, older, and more likely to be single than nonkinship adopting families (Barth 1994).

The foster-care system has provided invaluable assistance to children at risk. It deserves enhanced financial support, especially at a time when so many birth families are struggling to survive and may need to temporarily relinquish their child. Residential care facilities should be seen as positive alternatives for children in need. Residential facilities can fulfill a need for order, discipline, and rootedness in many young lives. They provide nonparental, well-qualified, and committed mentors who can turn around the lives of many youngsters who might wrongly be considered as hopeless cases. Residential care can be introduced into a child's life on a short-term basis at various points according to their needs, and can enhance family preservation, foster care, and adoption services. Young adolescents who can be taught fundamental principles such as "do no harm" and can benefit from the constructive adult guidance can experience the structure of residential care as liberating (Post et al. 1997).

Re-entry after reunification

Terling (1999) described the correlates of re-entry into child protective services for abused and neglected children reunited with their families. The correlates of re-entry included

1. *Type of abuse*: Neglect cases are the most common type of cases among both the family reunification cases and the re-entry cases. Among 59 cases of children who were examined after returning home, four had been repeatedly and severely physically and/or sexually abused, and previous documentation of risk of repeat abuse was present in those cases. Therefore, the mere presence of the severity of abuse warrants close attention during evaluation.
2. *Previous referrals*: The presence of previous referrals to a child protective agency is a strong indicator of the risk of re-entry. Also, inability of the parent to change after prior interactions with child protective services is a good indicator of the risk of re-entry. Of the re-entry cases, approximately 67% had previous referrals, versus 12% of non-re-entry.
3. *Substance abuse*: Some 50% of re-entry cases involved substance-abusing parents, as opposed to 20% for non-re-entry. Two important issues about substance abuse re-entry included (a) presence of a substance-abusing partner not in treatment; and (b) time allowed for recovery for the substance-abusing parent. Therefore in evaluating risk, importance should be given to perpetrators, partners, and their treatment, and the length of recovery in caregivers needs to be monitored for longer periods of time (months versus years).
4. *Parental competence* is the presence or absence of parental ability to provide an environment that is safe and healthy for the child to grow and develop. Parental competence can be impaired in (a) parents with low levels of intellectual functioning, thus possessing a deficit in their ability to process information and make decisions; and (b) parents who lack insight and do not understand or accept the agency's identification of their lifestyle and parenting as inappropriate. This lack of understanding interferes with their parenting skills and renders them incapable of changing their lifestyle/parenting to get their children back.
5. *Social isolation and negative relationships* such as an abusive spouse or a high level of family conflicts are significant predictors of re-entry.

There was less correlation of re-entry to parental income, child protective risk assessment by caseworkers, compliance, and family functioning assessment.

It is estimated that despite efforts by Child Protective Services to rehabilitate abusive and neglectful parents/families and make them suitable for the children, over one-third of these children return to the system due to additional maltreatment. The rate of children returning seems to be excessively high when dealing with the lives and future well-being of the children. Therefore, identifying for re-entry serves as a useful tool for practitioners and policy makers. Future research is needed to better understand the "whys" behind the successes and failures in order to develop policies and practices that do more than help some of these children, some of the time.

Research shows that although adopted children can have difficulties after placement, in the long run they progress well through their remaining childhood and into adult life. They tend to fare better than children brought up by their own parents in an abusive or neglectful environment, or in institutions, and are considerably better than children who have remained in long-term foster care. Several studies conducted in different countries to assess the effects of long-term foster care have all concluded that "Adoption, when available as an option, should be generally pursued rather than long-term foster care" (Mather 1999).

Mental health issues in adopted children

The emotional and behavioral adjustment of adopted children has received a great deal of attention as a result of the alleged over-representation of adopted children in mental health settings. The over-representation of adopted children and adolescents in clinical population research has varied widely. Several researchers have also suggested that the age of the child is an important factor; the older the child when placed in an adoptive home, the more likely the child is to have emotional and behavioral problems.

A study conducted by Borders et al. (1998), using a nationally representative sample of children in the United States, found no significant differences between adopted and nonadopted children on a range of adjustment variables. Brand and Brinich (1999) also concluded that a vast majority of adopted children showed patterns of behavior similar to those of nonadopted children.

The over-representation of adopted children in mental health settings found in earlier studies might be attributable to the presence of small groups of severely troubled adopted children in clinical samples. For the small group of severely troubled children and adolescents who had extensive behavior problems and were seen more frequently at the mental health centers, a better understanding of the factors that make these children vulnerable is an area of future research. Many factors such as (a) genetic predisposition to emotional and behavioral problems; (b) prenatal substance abuse by birth mothers; and (c) pre-adoption experiences such as neglect, abuse, or multiple placements may be contributing factors. This point needs to be emphasized because of the concerns that an error in interpretation could lead to pathologizing a very effective intervention for children. Most adopted children behave much like their nonadopted peers, and adoption remains a valuable and important social response to a complicated set of placement problems for children.

Role of child psychiatrist and medical practitioner in adoption assessment

Like all other parents, potential adopters need to have a thorough description of the children's past medical problems, their current health status, and their likely future needs. A comprehensive assessment of the child should be carried out to include the child's physical, emotional, developmental, and social status. Medical practitioners and child psychiatrists involved in adoption work assessments should have knowledge of the long-term consequences of child abuse and neglect. They should have an understanding of genetic illnesses that can be inherited from the birth parents, and of the long-term consequences of the parental lifestyles that may have involved exposure to alcohol, substance abuse, high-risk behaviors, and domestic violence. They should also be able to make recommendations on these children, and most often should be involved in considerable liaison with other health professionals, social services, foster parents, and adopters. It is important to recognize that if adoption is a real option for a group of very disturbed or disadvantaged children, then appropriately trained medical advisors with experience and knowledge in pediatrics and child mental health must be available to support this service.

SPECIAL ISSUES AND CONSIDERATIONS

Telling a child about being adopted

Telling a child about his or her unique route of entry into the family is a challenging process. In modern times it is recognized that children adapt more easily when they are aware of their birth circumstances. Therefore, parents are now advised openly to discuss adoption, not only with the child but also with relatives and friends. Then comes the question of when and how to discuss adoption. A 7- to 8-year-old child who possesses characteristics of logical thinking could more easily absorb and understand the adoption process than a younger child. Yet waiting until a child turns 7 years old is not recommended because

- Children ask questions earlier, and the parents would be forced to cover up or lie in some fashion.
- Sometimes children may inadvertently overhear comments about their adopted status from their relatives or friends.
- Children who look different from their parents often generate comments or questions from the public.
- Health-care providers ask questions regarding family history frequently in front of children.

The timing and substance of conversations about the child's adoption are challenging issues for both parents and providers. Most experts agree that open, life-long, and middle ground communication is the key to improving ego identity, smoothing the adaptation process, and building a child's positive self-image. One excellent method is to have a photo album of the child, beginning with the photographs of the adoptive mother and father going to the agency. It may be helpful to have another photograph of the parents' first contact with the child, along with a photograph of the mother carrying the child through the door into the new home. This provides a life-long continuity for the child's understanding of the adoptive "birthing" process into the adoptive home (Table 39.1).

The baby Byron case

This is a custody case that had considerable media coverage. This case highlights the problems most commonly raised in the transracial adoption debate.

> Byron, an African–American infant born addicted to heroin and cocaine, had been raised since July 1992—from the age of six days—by a Caucasian couple. This family had been selected to provide shelter for Byron on an emergency basis because his birth mother was unable to care for him. The foster family had their own biological child and two other adopted children. They were owners of a printing company. Byron's father was reportedly killed in an automobile accident in 1992. Byron's mother had four children who were cared for by two other families because she reportedly had neglected her children in the past. When Byron was a five-month-old, child protective officials tried to remove him from care of the Caucasian family and place him with an

Table 39.1 Stages of understanding adoption

Stage	Questions	Child's adoption related tasks	Goals for parent and child
Infants and toddlers (0–2)	"How do we begin?"	Adjusting to the transition to a new home Developing secure attachments	To become comfortable discussing adoption with others To use positive adoption language To become familiar with resources, support groups, books
Preschool (3–7)	"Where do babies come from?" "Where do I come from?" "Why or how did you choose me?" "Why don't I look like you?" "If you are in an adoptive family, can your birth parents or another family take you away?"	Learning about birth and reproduction Adjusting to initial information about adoption Recognizing physical differences within the family	To recognize child's egocentric thinking style To begin communicating about different ways children enter families To realize that despite the child's ability to parrot story, no abstract or conceptual understanding occurs yet To answer every question as faithfully as possible with positive adoption language To recognize physical differences but focus on similarities between child and the family To alleviate fears of losing adoptive parents by reassuring adoption is permanent
Middle childhood	"Why was I placed for adoption?" "Why didn't they keep me—didn't they like me?" "If you are adopted can you be un-adopted?" "If they didn't know how to take care of me, why didn't someone teach them?" "If they were poor why didn't someone give them money?" "Who do I look like?"	Understanding the meaning and implications of adoption Searching for answers regarding origin and reasons for relinquishment Coping with physical differences with the family Coping with the stigma of adoption Coping with peer reactions to adoption Coping with adoption related losses	To acknowledge sadness, anger, and grief associated with loss (7–11) of biological parents To assure child he or she is not bad or defective by offering actual reason for adoption To refrain from making negative comments about biological parents To offer factual information without embellishment To reassure that adoption is not a second choice To provide support groups and services for child
Adolescence	"Who am I?"	Exploring the implications and meanings of being adopted Connecting adoption to one's sense of identity Coping with racial identity Possibly searching for the biological family Coping with adoption related losses	To recognize child's abstract (12–17) thinking style To recognize identity difficulties of dealing with biological and adoptive parents To share adoption papers To continue use of support groups and services for child and parents
Young adult (18+)	"I want to meet my biological family"	Considering searching biological family Exploring implications of adoption as it relates to development of intimacy Coping with adoption related losses	To help child seek birth parents' To minimize parent's feelings of rejection To continue use of support groups and services for child and parents

African–American foster family. The Caucasian family objected, and the judge left the child with them on a short-term basis. When Byron was eleven months old, the judge once again ruled that Byron should continue to stay with the Caucasian family who expressed desire to adopt him. When Byron was seventeen months old the judge ruled that he should be returned to his biological mother, which in the judge's opinion was in the best interest of the child. In referring to criticism of his decision, the judge felt it was racist to conclude that an African–American woman was no good, and then to give Byron to the "nice, white, suburban couple." Byron was then returned to his biological mother who was reported to have undergone treatment for her substance-abuse problems and was living in a residential drug treatment center. The foster family reportedly felt that race was very much an issue in this case. They suggested that if the court had considered only the child's best interest, had visited Byron, and considered the birth mother's history of drug addiction, the decision would have been different. Some commentators argued that children are best reared in families where they will be taught coping skills. Others suggested it was important for any baby to be kept with his or her own race. However, in June 1994, the judge removed Byron from his biological mother after she admitted using drugs.

It is important to be mindful of the concepts of bonding and psychological parenting in the context of many adoption disputes where there might be considerable bonding or a unique affective connection between the child and the caregiver.

Silverman (1993) reviewed transracial adoption research studies published in the past 10 years, focusing on outcome in adolescence and adulthood. This included a comparison group, and they had their subjects placed for adoption at an early age. These studies assessed family integration, self-esteem, school performance, racial identity, and overall adjustment of the transracial adoptees.

The first of the studies in this group carried out by McRoy et al. (1984) reported that family integration and general adjustment were successful, and their self-esteem and academic performance were satisfactory. Marked differences emerged in the area of racial identity. The in-racial adoptees referred to themselves as black, and 56% of the transracial adoptees referred to themselves as mixed or part white. McRoy and her colleagues saw this racial group orientation among the transracial adoption children as problematic.

Simon and Alstein conducted the longest-running study between 1971 and 1991 (Simon and Alstein 1981; Simon 1994). There were again no impressive differences among the groups in regard to family integration, academic performance, self-esteem, and general adjustment. Most children were under the age of 3 years at the time of adoption in this study. During adolescence and later as adults, the transracial adoptees were aware of, and comfortable with, their racial identity. There was clear variability in their reference group orientation, however, as many of them dated Caucasian and preferred Caucasian friends.

It is important, therefore, for forensic experts or evaluators who participate in the transracial adoption context to make clear to the court the limitation of scientific-based data in this area. At the same time, the expert should tell the court what is known about parent–child bonding and the outcome of transracial adopted children. Undoubtedly, there will continue to be considerable disagreement about whether the best way to assure a promising future for an African–American child needing a permanent home is to seek qualified adoptive parents without regard to race. A thoughtful framework needs to be kept in mind as psychiatrists participate in this passionate debate of transracial adoption, which is of national importance.

Subsidized adoptions

When financial aid is given to adoptive parents after the adoption of a child, it is called *subsidized adoption*. The intent of such adoptions is to ensure permanent homes for children who would otherwise remain in foster care until they were adults. The amount of monthly payments and the length of time the subsidy is granted are left to the discretion of the social services commissioner, and can vary. A voluntary agency that has a child in foster care and wishes to recommend to the local department of social services adoption by the foster parents, with subsidy, may do so. The social services department may accept such recommendations, which include the amount of subsidy to be provided in the first year. After the adoption, the family is like any other family and is independent of the agency, except for annual evaluations of the need for continued subsidy.

Parental visitation after adoption

Visitation with a natural parent after adoption should be considered:

1. If there is a solid parent–child relationship, visitation after adoption should be explored and, if beneficial, implemented with consent of all parties, including the child.
2. The court should not force visitation after adoption without the consent of the adoptive parents and the child.
3. If visitation is provided, the court should retain jurisdiction and modify or vacate visitation where appropriate.

Grandparent's visitation after adoption

The paramount concern of the court in making its final decision as to grandparent's visitation must be the "best

interests of the child." The child's rights and wishes can be best considered if counsel represents them, and if the judge interviews the child as to his or her preferences. No petition for grandparent visitation should be dismissed without a hearing where the petition alleges that a relationship existed between the grandparent and the child. Prior to the hearing, a law guardian should be appointed to represent the interests of the child and his or her preferences, with the best interests of the child as a controlling factor. Several factors to be considered in the decision making include

1. The relationship between the grandparent and the child
2. The age of the child, and his or her wishes
3. The benefit to the child of a continued relationship with a grandparent
4. The recommendation of the law guardian
5. The contention and wishes of the adoptive parents
6. The extent to which visitation with grandparents could interfere with the new relationship of the child and the adoptive parents
7. In complex cases, the clinical assessment by a child psychiatrist

Child abuse and neglect

SUZANNE M. DUPÉE

INTRODUCTION

The maltreatment of children is not a new phenomenon. Empey et al. (1999) identified three periods in the history of childhood. In the pre-fifteenth century there was an *indifference to childhood.* From the fifteenth to eighteenth centuries there was a *discovery of childhood,* and in the nineteenth and twentieth centuries there was a *preoccupation with childhood.* The twenty-first century has accelerated the latter stage of *preoccupation with childhood.*

The Society for the Prevention of Cruelty to Children, the world's first child protective agency, was founded in 1874. Children were not offered protection by law until the late nineteenth century. Child abuse was mostly tolerated unless the case was extreme. The old saying, "spare the rod and spoil the child," validates parents who equate child abuse with good parenting. These parents often do not intend to damage the child but believe that corporal punishment will shape the child into a better adult. Many parents who engage in corporal punishment against their children might not be conscious of the cathartic benefit of letting out frustration (Averill 1983; Wolfe 1999; Averill 2012). Parents often justify their abuse by a false belief that corporal punishment is superior parenting. Other parents draw the line at some forms of corporal punishment such as spanking with objects.

The area of child abuse has evolved rapidly in the past 20 years. Cultural perceptions in the Western world regarding child maltreatment have changed dramatically. Parenting has become a highly valued skill for both mothers and fathers. The role of fathers has dramatically changed over the past 20 to 30 years, with today's father being more valued as an equal parenting figure. High levels of father involvement are associated with significant and highly desirable outcomes for children and families (Wilson and Prior 2011).

DEFINITIONS

The definition of child abuse encompasses physical abuse, emotional abuse, sexual abuse, and neglect. Several rare forms of child abuse occur in syndromes such as Munchausen by proxy and abuse of unborn children via intrauterine substance exposure—fetal abuse.

Physical abuse is defined as the nonaccidental physical injury of a child under 18 years old by a person who is responsible for the child's welfare (U.S. Department of Health and Human Services 2014). The injury is considered abuse regardless of whether the caregiver intended to hurt the child. Physical discipline such as spanking is not considered abuse as long as it is reasonable and causes no bodily injury (American Psychiatric Association 2013).

Child sexual abuse is defined as the use of the child as an object of gratification for adult sexual needs or desires. *Incest* refers to the sexual exploitation of a child by another family member. Sexual abuse includes noncontact exploitation of a child by a parent or caregiver, e.g., enticing or threatening the child to participate in sexual acts for the sexual gratification of others, even if there is no direct physical contact between the child and the abuser (American Psychiatric Association 2013).

Emotional or psychological abuse is defined as nonaccidental verbal or symbolic acts by a parent or caregiver that result or have potential to result in significant psychological harm to the child, e.g., humiliating, disparaging, belittling, scapegoating, abandoning, or threats of abandonment or harm or close confinement (the restriction of movement, e.g., binding the child's limbs to furniture or object, or confining the child to a small enclosed area, e.g., the closet). Other forms of emotional abuse include withholding basic needs such as food, shelter, sleep, or necessities as a form of punishment or coercing the child to inflict pain on himself or herself and disciplining the child excessively (i.e., at an extremely high frequency or duration even if it is not at the level of physical abuse) through physical or nonphysical means. Garbarino et al. (1986) identified five types of psychological maltreatment more likely to occur in families with atmospheres full of stress, tension, and aggression, and these are summarized in Table 40.1 (Garbarino et al. 1986).

Neglect is defined as any confirmed or suspected egregious act or omission by a child's parent or caregiver that

Table 40.1 Five types of psychological maltreatment

1. Rejecting—the child's legitimate need for a relationship with both parents is rejected.
2. Terrorizing—the child is bullied or verbally assaulted into being terrified by the target parent.
3. Ignoring—the parent is emotionally unavailable to the child, leading to feelings of neglect and abandonment.
4. Isolating—the alienating parent isolates the child from normal opportunities for social relationships.
5. Corrupting—the child is used as an agent of aggression against the target parent, with the child actively participating in deceits and manipulations for the purpose of harassing and persecuting the other parent.

deprives the child of basic age-appropriate needs and thereby results, or has reasonable potential to result, in physical or psychological harm to the child. Child neglect can be classified as physical, educational, and emotional neglect (U.S. Department of Health and Human Services 2014). Examples of physical neglect include abandonment, refusal of health care, delay in health care, expulsion from the home, custody-related issues, inadequate supervision, driving while intoxicated, or leaving a child unattended in a motor vehicle.

Munchausen syndrome by proxy is defined as a pattern of behavior in which a caregiver fabricates, exaggerates, or intentionally inflicts mental and/or physical health problems on the person in the caregiver's care. The American Professional Society on the Abuse of Children (APSAC) created the term "Pediatric Condition Falsification" (PCF) for the diagnosis of the abuse of the child. Factitious disorder by proxy (FDP) is used to diagnosis the caretaker who harms the child through PCF with the motivation of self-serving psychological needs (Schreier 2002). Munchausen syndrome by proxy is a descriptor for the disorder that contains both elements.

Fetal abuse is defined as the ingestion of substances during pregnancy that may have serious consequences to the developing fetus. The U.S. Supreme Court case *Ferguson v. City of Charleston* (2001) dealt with the question of the threat of criminal sanctions to deter a pregnant woman from using cocaine. Some states have passed laws mandating incarceration and rehabilitation of pregnant women using drugs during pregnancy. The question of prosecution and confinement has been criticized for a violation of the mother's rights (Fentiman 2006).

EPIDEMIOLOGY

Child maltreatment is a prevalent sociological problem as indicated by the millions of suspected reports of child abuse by the National Child Abuse and Neglect Data System (NCANDS) (U.S. Department of Health and Human Services 2012, 2014) through the Department of Health and Human Services. Despite the millions of reports to child protective agencies, the true statistics of child abuse are likely vastly underestimated due to nondisclosure within families.

In 2012, over 680,000 child abuse reports were made to Child Protective Services. Mandated reporters made 62% of reports. The most common form of child abuse was neglect. Figure 40.1 (U.S. Department of Health and Human Services 2014) provides a graphic overview of the percentage for each type of child abuse reported.

In 2012, an estimated 1640 children died from child maltreatment (2.2 per 100,000 children). Of those who died 70% experienced neglect, and 44% experienced physical abuse either exclusively or in combination with another form of maltreatment. Boys were at more risk of fatal outcome from child abuse than girls, with a rate of 2.5 per 100,000 and 1.9 per 100,000, respectively.

The youngest children were the most vulnerable, with 27% of reported victims under 3 years old and children under 1 year having the highest rate of victimization (21.9

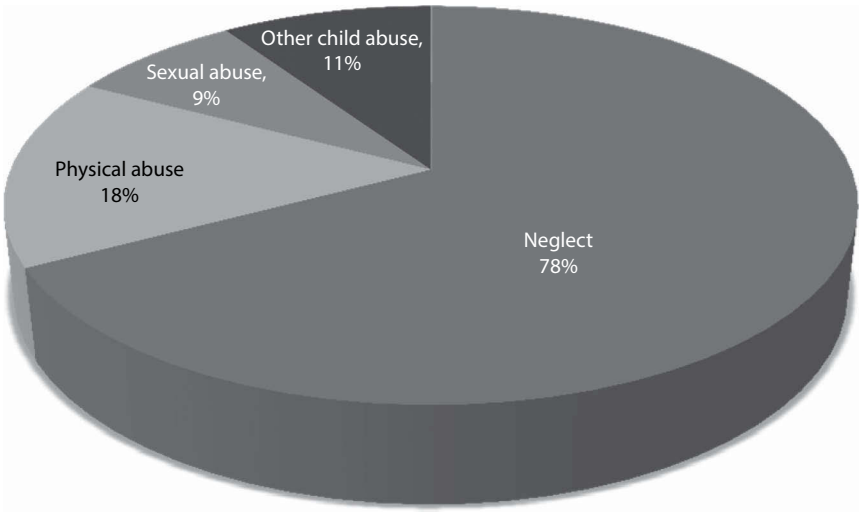

Figure 40.1 Types of child abuse and neglect.

per 1000 children). Children aged 3–5 years comprised 20% of victims. Racial differentiation of child abuse victims shows a high rate of abuse among native and Alaskan Indians. Parents dominate the most common perpetrators of child abuse, comprising 80%. Six percent were relatives other than parents, and 4.2% were unmarried partners of parents. Eighty-two percent of perpetrators were between 18 and 44 years old. Fifty-four percent were women, and 45% were men.

ETIOLOGY AND RISK FACTORS

The etiology of child abuse cannot be narrowed down to a specific causative factor; however, there are often similar combinations of risk factors common to child abuse victims, and these are noted in Table 40.2.

Interventions for treating family systems might involve interagency collaboration. It is critical to address the causes rather than the symptoms in order to effectuate long-term change and to break the cycle of violence and dysfunction in abusive families. Targeting one stressor (e.g., unemployment) could have a domino effect on improving other stressors (e.g., housing) and can lead to a more stable home environment for the child and decrease the risk of abuse. Prevention and education remain the stalwart of reducing the incidence of child abuse. Children in Early Head Start programs are at lower risk of being abused (Zhai et al. 2013).

PRESENTATION AND CLINICAL FINDINGS

Physical abuse

Physical abuse is often the most overt type of abuse. Bruises, cuts, burns, welts, and scars are frequently visible to others such as teachers, doctors, family members, and friends. Physical abuse results in a wide range of injuries that are characteristically more severe than could be reasonably attributed to the claimed cause (Ballin 1985). Bruises may be the first and only visible sign of physical abuse. It is true that most children sustain minor injuries and bruises in their normal play. Distinguishing whether a bruise is due to normal activity or child abuse is often very difficult, and dating of bruises has been shown to be highly inaccurate (Bariciak et al. 2003; Maguire and Mann 2013).

Table 40.2 Factors increasing the risk of child abuse

- Poverty
- Lack of education
- Serious marital problems
- Frequent changes of addresses
- Violence between family members
- Lack of support from the extended family
- Loneliness and social isolation
- Unemployment
- Inadequate housing
- Very high expectations of the child and what the child should achieve
- Parent who was abused as a child
- Lack of knowledge and skills in bringing up children
- Low self-esteem
- Low self-confidence
- Depression, alcohol, and/or drug abuse
- Mental or physical ill health
- Work pressures

With rare exception, nonambulatory infants should not have any bruising (Sugar et al. 1999). The presence of a bruise in an infant should prompt further investigation for nonaccidental trauma or an underlying medical illness. Bruises over soft tissue areas in nonmobile infants that carry the imprint of an implement and multiple bruises of uniform shape are suggestive of abuse (Maguire et al. 2005). Pattern of burns specific to abuse include glove and stocking distribution, perineal and buttock burns due to submersion, absence of splash burns, and outlines of burns due to cigarette or an identifiable object (Andronicus et al. 1998). Kemp et al. (2014) found the majority of intentional non-scald contact burns are due to cigarettes, irons, hairdryers, and heaters. Single or multiple circular, deep-cratered burns are consistent with cigarette burns.

Fractures are common in both nonabused and abused children. Differentiation of fractures includes multiple fractures, bilateral long bone fractures, and fractures in different stages of healing or in developmentally disabled children. Leventhal et al. (2010) found an overlap between traumatic brain injuries and fractures attributable to abuse. Ravichandiran et al. (2010) found that 20% of abuse-related fractures are missed during the initial medical visit. Fractures of long bones such as the humerus, tibia, and fibula are commonly seen in abused children because the limbs are often used as a handle when young children are thrown or shaken.

Classic metaphyseal lesions (CMLs) or "bucket handle fractures" of the tibia, femur, and proximal humerus are thought to be caused by forceful shaking or twisting of a child. Other than children with rickets, these fractures carry a high predictor of child abuse during the first year of life (Kleinman et al. 1986, 2011). Buckle fractures of the fingers and toes indicate forced extension. Nonextremity fractures such as skull and ribs should alert the physician to the possibility of child abuse. However, no specific pattern of fractures is pathognomonic of abuse, and diagnosis is incomplete without a skeletal survey and investigating for other evidence of abuse (American Academy of Pediatrics 2009; Swoboda and Feldman 2013).

Abusive head trauma (AHT) or "shaken baby syndrome" is a leading cause of morbidity and mortality in infants and young children (Herman et al. 2011). These children present to the emergency department in subtle or dramatic ways with conditions ranging from lethargy, irritability, vomiting, rigidity, and decreased appetite, to seizures, altered consciousness, and respiratory distress due to subdural

hematomas and/or retinal hemorrhages (Westrick et al. 2015). Missing the diagnosis of AHT can be fatal. Jenny (1999) found that 30% of AHT cases were missed, and 40% experienced medical complications due to the missed diagnosis. They found that four out of five deaths might have been prevented with earlier recognition. Abusive head trauma is 100% preventable with parent education about the risks to babies when they are shaken and with treating parental stress.

Emotional abuse

Unlike physical abuse and sometimes sexual abuse, emotional abuse leaves no visible scars. From a psychiatric perspective the signs and symptoms are even more obtuse and vague. The child might present with fear or anxiety related to or reluctance to return home to his or her caregiver. Child emotional abuse (CEA) is associated with serious and negative emotional and behavioral consequences (Hart et al. 1997; Egeland et al. 2000; Yates 2007). Research in the area of emotional child abuse has yielded more information related to neurodevelopment, psychological impact on children, and parent–child interactions.

Child emotional abuse had been ill defined and therefore efforts to identify and ameliorate its detrimental effects were hampered (Cicchetti 1991; Iwaniec 1995; Yates 2007). Slep et al. (2011) attempted to develop operationalized criteria for CEA to improve future research. Abusive parental behaviors such as humiliating, terrorizing, and scapegoating fell out of the scope of good caregiving. The researchers admitted some types of parental verbal aggression, such as yelling, would categorize the majority of parents as having engaged in acts of emotional aggression. The potential impacts were emotional rather than physical and included psychological harm, more-than-inconsequential fear reactions, and significant psychological distress. They found that it was difficult to capture every single important element of child emotional abuse that is being raised in the literature (Glaser 2002).

Egeland et al. (2000) demonstrated the relationship between CEA and insecure attachments to caregivers and declines in cognitive and motor competence in the first years of life in a high-risk poverty sample. By school age, CEA was associated with high levels of negativity, low academic achievement, impulsivity, low self-esteem, and difficulty forming friendships, depression, and suicidality (Maguire et al. 2015). CEA has been associated with not only behavioral and psychological sequelae but also changes to neurodevelopment. The understanding of the neurobiology of the stress responses in the developing brain has led to the discovery of relationships between parental caregiving, attachment, and the adverse effects of CEA. Research has consistently shown that early adversity interferes with the limbic–hypothalamic–pituitary–adrenal axis and the norepinephrine–sympathetic–adrenal–medullary system by altering stress responses (Teicher 2002; Bugental et al. 2003; Teicher et al. 2003; Martorell and Bugental 2006).

Maternal verbal abuse during childhood has been associated with a markedly higher risk for development of borderline, narcissistic, obsessive–compulsive, and paranoid personality disorders (Johnson et al. 2001). Verbal abuse may also have more long-lasting consequences than other forms of abuse (Ney 1987). The combination of verbal and other forms of abuse had the greatest impact on children by affecting their enjoyment for living and hope for the future.

Neglect

Neglect is the most common form of child abuse. Unlike physical or sexual abuse, neglect is often an act of omission by caregivers failing to fulfill the obligations of caring for the child. Child neglect can have long-term serious and deleterious effects on children's cognitive, socio-emotional, and behavioral development (Erickson and Egeland 2002; Hildyard and Wolfe 2002).

Three major subtypes of neglect identified are physical, psychological, and environmental. Examples of physical neglect include inadequate supervision, refusal or delay in seeking health care, exposure to avoidable hazards, and driving with the child while intoxicated. Psychological neglect includes a parent providing inadequate nurturance and affection or exposing the child to spousal abuse. Environmental neglect includes such behaviors as failure to enroll children in school, chronic truancy, or inattention to special educational or developmental needs.

Presentations of neglect can be obvious, such as malnutrition or inappropriate clothing or hygiene, or are subtle and insidious, such as fatigue, low self-esteem, depression and withdrawal, or failure to thrive and developmental delays. Children suffering from neglect are at risk of developing insecure attachments (Baer and Martinez 2006).

Munchausen syndrome by proxy

Munchausen syndrome by proxy is a rare entity. Although the term Munchausen syndrome by proxy is widely used, it has not been included as a diagnosis in the *Diagnostic and Statistical Manual of Mental Disorders*, 5th edition (*DSM-5*). Factitious Disorder Imposed by Another is the *DSM-5* diagnosis that encompasses the elements of Munchausen syndrome by proxy. In the United Kingdom, Munchausen syndrome by proxy is known as Fabricated or Induced Illness by Caregivers.

The American Professional Society on the Abuse of Children (APSAC) developed specific diagnostic criteria that encompass the term Pediatric Condition Falsification (PCF) as the diagnosis of the abuse of the child akin to Munchausen Syndrome by Proxy. Factitious Disorder by Proxy (FDP) is used to describe the diagnosis in the caretaker who harms his or her child through PCF with the motivation of self-serving psychological needs. Critical differentiating criteria from malingering include the absence of secondary gain, and ruling out of other mental and physical illnesses.

Mothers are the most common perpetrators of Munchausen syndrome by proxy (Meadow 1989; McClure et al. 1996; Malatack et al. 2006). About 10% of fathers are perpetrators (Shaw et al. 2008). Male perpetrators are more likely to kill their children than female perpetrators (Meadow 1982; Rosenberg 1987; Schreier 2004). Mothers frequently have nursing training and present as devoted, loving caregivers who often refuse to leave their child during procedures. The physician is an unknowing agent in unwittingly inflicting harm on the child through surgeries, medications, and procedures. Mothers are often so convincing that physicians defend against the mother. The perpetrating mother appears less concerned about the child's health than the medical staff and procedures. Female perpetrators often develop a good rapport or even close friendships with medical staff (Beard 2007; Shaw et al. 2008). Male perpetrators do not form close bonds with medical staff and might present as demanding, overbearing, or litigious (Shaw et al. 2008).

The abuse always occurs in the caregiver's presence, and there is no gender preference. The average age of the victim is 3 years old, and victims are rarely older than 6 years old (Fulton 2000). Presentation can involve almost every organ system and is often multisystem. The most common presentations of Munchausen syndrome by proxy are bleeding, diarrhea, seizures, apnea, fever, and rash. As an example, Munchausen syndrome by proxy should be considered in a child with apnea whose sibling died or if the apnea only occurs in the presence of one person (Forsyth 1996).

CHILD SEXUAL ABUSE

Child sexual abuse is an international problem. A plethora of research has evolved in the area of child sexual abuse over the past 30 years. Cases such as the multimillion dollar 6-year criminal trial of the McMartin preschool in Los Angeles in the 1980s prompted research about child witnesses, especially in the area of memory and suggestibility. The true incidence of child sexual abuse is unknown due to lack of or delay in reporting (London et al. 2008). Stoltenborgh et al. (2011) conducted a comprehensive meta-analysis of child sexual abuse cases reported in 217 publications between 1980 and 2008 including 331 independent samples with a total of almost 10 million participants. They found that the overall estimated child sexual abuse prevalence was 127/1000 in self-report studies by victims and 4/1000 in informant studies from professionals observing children such as doctors and teachers. Self-reported child sexual abuse was more common among females (180/1000) compared to males (76/1000). The lowest overall rate was found in Asia, and the highest rate for girls was in Australia and for boys in Africa. They found that child sexual abuse is a global problem.

Justice Powell of the U.S. Supreme Court stated in his opinion in the incest case of *Pennsylvania v. Ritchie* (1987), "Child abuse is one of the most difficult crimes to detect and prosecute, in large part because there often are no witnesses except the victim." There are often no injuries or physical evidence to prove the victim's allegations. Ultimately the verdict in most cases relies "heavily on a courts adoption of a particular story, one that makes sense, is true to what the listeners know about the world and hangs together" (Scheppele 1989).

Table 40.3 Types of sexual abuse

- Verbal sexual propositions
- Sexual harassment
- Voyeurism
- Exhibitionism
- Fondling
- Masturbation
- Vaginal intercourse
- Oral intercourse
- Anal intercourse
- Penetration
- Child pornography
- Female genital mutilation

Child sexual abuse encompasses a wide definition of sexual activities that are summarized in Table 40.3.

SPECIAL TOPICS IN CHILD SEXUAL ABUSE: CHILD SEX TRAFFICKING, CHILD PORNOGRAPHY, FEMALE GENITAL MUTILATION, AND SEXTING

Child sex trafficking, child pornography, and female genital mutilation are topics currently being discussed in the international forum. Child sex trafficking and child pornography are global public health problems. The 1996 Declaration and Agenda for Action for the First World Congress Against the Commercial Sexual Exploitation of Children (CSEC) provided a working definition of the commercial sexual exploitation of children (Adams et al. 2010). Commercial Sexual Exploitation of Children is defined as sexual abuse of a minor for economic gain. The National Human Trafficking Resource Center has a national hotline to report abuse. The U.S. Department of Justice estimated about 100,000 to 300,000 children entered the U.S. commercial child sex trade (http://www.traffickingresourcecenter.org). The American Professional Society on the Abuse of Children identified barriers to detecting child victims (Estes and Weiner 2001; Zimmerman 2006; Gragg et al. 2007; Clawson and Dutch 2008; Crane and Moreno 2011; Greenbaum et al. 2013).

Child pornography

Child pornography is a serious, prolific, multimillion dollar, worldwide business that almost invariably leaves a permanent, digital cyber record of child abuse. This is exacerbated by unfiltered and unmonitored circulation on the World Wide Web. The emotional damage to a child victim is extremely difficult to assess in monetary compensation due to the infinite reaches of distribution. Seto et al. (2006) found that child pornography offending is a stronger

diagnostic indicator of pedophilia than is sexually offending against child victims.

In the U.S. Supreme Court case, *Paroline v. US* (2014) the victim was 8 years old when she was sexually abused by her uncle who produced child pornography of his niece which was sold and distributed on the Internet. He was ultimately prosecuted and sentenced to a lengthy prison sentence and ordered to pay $6000 to the victim. The victim initially benefitted from therapy and was deemed normal. Her emotional status, however, significantly declined as a teenager when she discovered trafficked images of herself on the Internet. The victim sought restitution against Petitioner *Paroline* under the Violence Against Women Act of 1994, §2259 (reauthorized in 2013) which requires District Courts to award restitution for certain federal criminal offenses, including child pornography possession. Paroline possessed child pornography images of the victim, but he never met the victim. The Court held that restitution is proper only to the extent the defendant's offense proximately caused a victim's losses and that defendants should only be liable for the consequences and gravity of their own conduct, not the conduct of others.

Sexting has become another new social phenomenon with the explosion of social media and smartphones among latency-aged children, tweens, and teens. Mitchell et al. (2012) conducted a study of 1560 youth Internet users, ages 10 through 17. They found that 2% of youth had appeared in or created nude or nearly nude pictures or videos but only 1% were sexually explicit. Seven percent of participants received nude or nearly nude images of others while 6% reported receiving sexually explicit images. Few youth distributed these images. They concluded that sexting is far from a normative behavior for youth. Further, teens should be educated about the legal consequences of sexting and what to do if they receive a sexting image, because the law can be punitive and harsh. Child pornography laws often intersect with adolescent sexting, occasionally resulting in catastrophic outcomes in which teens are convicted of sex offenses and required to register as sex offenders for decades to come (Calvert 2009; Richards and Calvert 2009; Judge 2012).

Female genital mutilation

The World Health Organization defines female genital mutilation (often referred to as female circumcision) as "includes procedures that intentionally alter or cause injury to the female genital organs for non-medical reasons" (http://www.who.int/mediacentre/factsheets/fs241/en/). Over 125 million women and girls have undergone the practice. Female genital mutilation has been defined as a violation of human rights in many countries, with laws being passed to outlaw the practice. In Senegal, about 20% of the female population is estimated to be circumcised. Female genital mutilation is practiced on the girls from infancy to 15 years old (http://www.WHO.int). Behrendt and Moritz (2014) found an increased prevalence of post-traumatic stress disorder and other psychiatric syndromes in women who underwent female genital mutilation.

CHILD SEXUAL ABUSE INTERVIEW GUIDELINES

Many organizations have set forth guidelines for forensic interviews of children. The American Academy of Pediatrics (AAP) published Guidelines for the Evaluation of Sexual Abuse in children in 2005. The American Academy of Child and Adolescent Psychiatry (AACAP) published Guidelines for the Clinical Evaluation of Children in 1988 (Bernet 1997) and a Policy Statement about Protecting Children in Abuse Investigations and Testimony in 1989.

Guidelines were also developed through nonmedical organizations or agencies. The National Children's Advocacy Center developed RADAR (Recognizing Abuse Disclosure types and Responding). CornerHouse developed the CornerHouse Forensic Interview Protocol—RATAC (Rapport, Anatomy Identification, Touch Inquiry, Abuse Scenario, Closure)—which is included in the Finding Words training curriculum. The RATAC protocol is the most widely used protocol in the United States (Faller 2014).

The American Professional Society on the Abuse of Children (APSAC) developed the Practice Guidelines for Psychosocial Evaluation of Suspected Sexual Abuse (APSAC 1990, 1997, 2012) , the Memorandum of Good Practice, and the revision, Achieving the Best Evidence. Many of these organizations also developed training programs for forensic interviewers. Additionally several states—Washington (Harborview Center for Sexual Assault and Traumatic Stress), Michigan (State of Michigan Governor's Task Force on Child Abuse), and Oregon (Oregon Department of Justice 2012)—developed interview guides.

In 2000, the *Eunice Kennedy Shriver* National Institute of Child Health and Human Development (NICHD), part of the National Institutes of Health (NIH) and the U.S. Department of Health and Human Services (USDHSS), developed a protocol for child sexual abuse allegations called the NICHD Investigative Interview Protocol. Due to the international collaboration in 1993, the NICHD has access to over 40,000 forensic interviews and has dramatically improved the quality of interviewing children in sexual abuse cases. The NICHD protocol has been translated into multiple languages and is available online. The NICHD investigative interview protocol technique is an 11- or 12-phase protocol as summarized in Table 40.4.

CHILD ABUSE AGENCIES

The Child Abuse Prevention and Treatment Act (CAPTA) provides federal funding to States to improve child protective services and interagency collaboration in the areas of investigation, prevention, assessment, mental health, education, prosecution, and treatment. CAPTA was originally enacted in 1974 and amended several times, most recently in 2010. Through CAPTA, reporting by mandated reporters was expanded to numerous professions and not just limited to medical professionals. CAPTA also expanded the types of abuse reported (Faller 2014).

Table 40.4 National Institute of Child Health and Human Development Protocol Phases

1. Systematic introductions
2. Rapport building
3. Training in episodic memory
4. Transition to substantive issues using open-ended to more closed-ended questions
5. Investigating the event
6. Break
7. Eliciting information not mentioned by the child
8. If the child fails to mention expected information
9. Information about disclosure
10. Closing
11. Ending on a neutral topic

Child Advocacy Centers (CAC) were developed in 1985 as a child-friendly place where sexual abuse victims and their families would undergo a single interview by forensically trained professionals. There are currently over 900 CACs in all 50 states and in 25 countries (National Children's Advocacy Center).

All states in the United States have child abuse reporting agencies with statutes mandating reporters such as health-care workers, teachers, and childcare providers. The operative legal term is "suspicion" of child abuse rather than "confirmation" or "investigation" of child abuse. Child abuse victims do not often reveal details or presence of abuse. Because child abuse is often kept behind closed family doors, identification by professionals such as teachers, physicians, and childcare workers is the first step toward intervention. Abusive families often do not welcome state agencies into their homes and become defensive about the allegations. Parents might influence children to lie to officials about abuse, thus leading victims to more reprisal if they confide family secrets. Children are often afraid of being separated from their parents and recant accounts of abuse.

Selph et al. (2013) found that risk assessment and behavioral interventions in pediatric clinics reduced abuse and neglect outcomes for young children. Common strategies for child maltreatment are parent education and home visiting programs. Research has found the most effective parent training programs provide families opportunities for practicing parental skills in their own home (Kaminski et al. 2008).

In 1993, an international meeting of experts on child sexual abuse was held to develop consensus about how child sexual abuse allegations could be investigated most productively (Lamb 1994). In the 1990s, a number of interview protocols were developed (Faller 2014). Several interview protocols have emerged ranging from scripted to semi-structured. Faller (1993) organized eight categories and key validation indicators to assess the veracity of sexual abuse allegations. Important criteria of each factor are identified to assess in child sexual abuse evaluations, and these are outlined in Table 40.5.

Table 40.5 Eight categories and key validation indicators assessing veracity of sexual abuse allegations

1. Timing and circumstance of disclosure
   a. Initial disclosure is spontaneous
   b. Absence of undue influence so ulterior motives to fabricate
   c. Anxiety or hesitancy regarding divergence of the sexual abuse
2. Language congruence with developmental level
   a. Description based on the child's point of view all prospective
   b. Use of age-appropriate vocabulary and speech
3. Quantity and quality of details
   a. Explicit, detailed account including contextual details, for example, where, when, what one was wearing, where others were during the abuse
   b. Unusual or superfluous details
   c. Idiosyncratic and sensorimotor details
   d. Increasingly progressive sexual acts
4. Appropriateness of sexual knowledge based on developmental level
   a. Sexual knowledge that exceeds the child's developmental level
   b. Precocious knowledge of sexuality
   c. Premature eroticization
5. Repetition over time: internal and external consistency
   a. Consistency of core elements
   b. Consistency of the reporting salient details
   c. Consistency with other statements
6. Description of offender behavior
   a. Coercion and tricks
   b. Bribes or rewards
   c. Element of secrecy
   d. Statements about telling or not telling
   e. What the offender said to obtain participation
   f. Pressure to recant
7. Plausibility of abuse
   a. Description recounted in a varied and rich manner as opposed to a rote recitation
   b. Circumstantially congruent description of being sexually abused
8. Emotional reaction of the child during the interview
   a. Emotional reaction consistent with accusations
   b. Emotional state consistent with the abuse

SPECIAL TOPICS: DOMESTIC VIOLENCE, PARENTAL ALIENATION, FALSE ALLEGATIONS

Domestic violence

Over 40 years of research regarding the relationships of children who are abused by their parents showed that

there is a correlation between children exposed to domestic violence (also referred to as Intimate Partner Violence or IPV) and physical abuse against the children (Appel and Holden 1998). The U.S. Bureau of Justice statistics indicated the rate of IPV in 2010 was 3.6 per 1000 (United States Department of Justice Intimate Partner 2013). Children are present in many households where IPV occurs and, therefore, are exposed to witnessing their parents being injured or emotionally abused. Children in IPV households might not directly witness the violence but are aware of its existence in their home (Fantuzzo et al. 1997; Holden et al. 1998; Fantuzzo and Mohr 1999). Over 15 million children in the United States live in domestically violent households (McDonald et al. 2006). The relationship between IPV and child abuse has been a topic of research for many years. Moore (1975) discovered that 13% of children from 23 domestic violent families were hurt or threatened with violence. The U.S. Department of Justice reported children are present in about a third of domestically violent households (or one in 320 households). Fifteen percent of child fatalities were exposed to domestic violence with the caregiver being either the perpetrator of or the victim of the domestic violence (Margolin and Vickerman 2011).

Domestic violence in the household can lead to posttraumatic stress disorder (PTSD), especially if the violence is often repetitive and ongoing without a discrete precipitating traumatic event. The child's traumatic reactions may generalize to less serious demonstrations of anger and conflict and even verbal aggression (Margolin and Vickerman 2011). The child's sense of safety is continuously challenged as there is no escape from the trauma. Parents who engage in domestic violence also suffer increased stress that might adversely affect their parenting (Roberts et al. 2013). Mothers of young children in domestically violent relationships are at increased risk of depression and stress (Huth-Bocks et al. 2001), leading to impaired parenting. Often one salient traumatic domestic violent episode launches them into the child welfare system even if the pattern of domestic violence in the household is long term.

The cycle of domestic violence has been well documented over decades. Men who witness domestic violence in their families of origin are at increased risk for IPV (O'Leary et al. 2007). There is a known relationship between witnessing child abuse and neglect and the risk for IPV perpetration and victimization as an adult (Feerick et al. 2002; McKinney et al. 2009; Widom et al. 2014). Widom et al. (2014) found childhood neglect increases a person's vulnerability to domestic violence victimization in adulthood. The two most consistent predictors of domestic violence perpetration were child and adolescent abuse and family of origin.

The forensic mental health expert is called on to assess the effects of domestic violence in children, the relationship of the domestically violent parent with the child, or the parenting competency of the victim and perpetrators. Forensic evaluators should be familiar with local, state, and federal laws pertaining to domestic violence and child victims.

Parental alienation

Parental alienation syndrome (PAS) has been described as a form of emotional child abuse. PAS was a topic considered for inclusion in the *DSM-5* but ultimately was not included. PAS is a controversial phrase coined by Richard Gardner in 1985 (Gardner 1985) to describe the programming of a child in order to be alienated from the target parent. The term "parental alienation" has replaced "Parental Alienation Syndrome." Parental alienation is a simplified and descriptive term for the dynamic that frequents family court proceedings in high-conflict family law cases.

The primary manifestation of parental alienation is the child's unjustified campaign of denigration against a parent resulting from the combination of a programming (brainwashing) parent's indoctrinations and the child's own contributions to the vilification of the target parent. When true parental abuse and/or neglect is present, the child's animosity may be justified, and so the parental alienation syndrome explanation for the child's hostility is not applicable (Gardner 2002). The literature on parental alienation categorizes degrees of alienation, depending on the severity of the effect in terms of duration, magnitude, and intransigence of the child's rejection of the alienated parent (Baker 2006). The literature has moved away from using Gardner's labels of Parental Alienation Syndrome to using terms and phrases such as alienating behaviors, gatekeeping, alignments, and realistic estrangement (Fidler and Bala 2010). Realistic estrangement between parents occurs when the child's resistance or refusal might be the result of witnessing domestic violence, or experiencing abuse and/or neglect by the rejected parent.

Girls and boys experience alienation equally, although adolescents are more likely to become alienated than younger children (Kelly and Johnston 2001). Mothers or fathers can be alienated from their children (Bala et al. 2010). Most commonly, the primary custodian of the child is the perpetrator of alienation. However, it is difficult, but not impossible, for a parent with limited contact with the child to alienate the child from the primary custodial parent (Fidler and Bala 2010).

Raising parental alienation as an issue in Family Court usually corresponds with allegations of child abuse by the alienating parent. The wheels of justice slow down substantially when alienation and abuse are at issue. Strategically, this often gives the alienating parent more time and access to the children to perpetuate their alienating behaviors. Conversely the alienated parent becomes more marginalized with time until usually a series of mental health professionals evaluate, treat, and provide more guidance and education to the Court about the disturbed family dynamics. Forensic findings can include false allegations, underlying mental illness (of either parent), justifiable alienating behavior due to bona fide child abuse, or somewhere in between. The legal outcomes might range from a reversal of custody by placing the child with the targeted parent while the alienated parent seeks mental health treatment.

Whatever the findings, the effects of true alienation can last a lifetime and contribute to self-esteem problems, depressive disorders, a trend toward alcohol abuse, and insecure attachment styles as adults (Baker 2005a,b, 2006, a; Baker and Ben-Ami 2011; Ben-Ami and Baker 2012).

False allegations

False allegations of child abuse, unrelated or in combination with parental alienation, arise in several legal settings—family court, criminal court, and dependency court. In criminal cases and dependency cases, the risks to the family could be prosecution and foster care placement if the children are removed from their parents' custody. False allegations in Family Court might stem from innocent misperceptions and inaccurate interpretations (Perry 1995), such as a father bathing a young daughter who innocently reports touching of the genitals to a mother in a high-conflict custody case. Additionally, lack of child sexual development can lead to false child sexual abuse allegations that can halt the legal process and deny access of an innocent parent to his or her child. False allegations in Family Court are akin to throwing mud at the wall and seeing what might stick. Although the mud might not stick, the stain can be long-standing.

Recanting of allegations of child abuse is not as common as delaying reporting. In the U.S. Supreme Court case *Martinez v. Ryan* 2012, the 11-year-old female victim recanted accusations of sexual abuse (despite DNA evidence) due to the mother's reluctance to lend support to the victim's claims.

MULTIDISCIPLINARY INTERVENTION FOR EVALUATION AND TREATMENT

Maltreated children present with an extensive range of symptoms, behaviors, and disorders. Abused children are at risk of serious emotional, developmental, behavioral, and learning disorders. Comprehensive screening and evaluation of medical, developmental, educational, and psychiatric issues should be performed on all children suspected of abuse. Appropriate school placement, parental training, and education are part of a multidisciplinary approach. Children might present without current symptoms but still be at risk for developing psychiatric disorders in the future.

Psychological interventions have been shown in short-term clinical trials to ameliorate the consequences of CSA. Trauma-focused cognitive behavioral therapy for victims of child sexual abuse have demonstrated efficacy in decreasing negative psychological effects (Cohen et al. 2000; Macdonald et al. 2006; Scheeringa et al. 2011; Deblinger et al. 2012; Mannarino et al. 2012).

EMDR (eye movement desensitization and reprocessing) is another modality used to treat trauma victims. The majority of patients treated with psychotherapy and/or EMDR for PTSD recover or improve (Bradley et al. 2014). However, PTSD is often a chronic disorder, and the majority of patients continue to have residual symptoms. Psychopharmacologic interventions are used to target disorders related to trauma from abuse, e.g., selective serotonin reuptake inhibitors (SSRIs) are used to treat symptoms of depression, anxiety, and PTSD.

Forensic psychiatric evaluation of child abuse victims is dependent on the allegations and nature of the case, because there can be a broad range of symptomatology and presentations. In cases of child sexual abuse, a thorough and multidisciplinary approach is necessary to assess both the victims and perpetrators. Evaluations of child sexual abuse victims should be handled in a systematic manner by trained interviewers to minimize trauma to the child and the family. Ideally the victim should undergo only one mental health videotaped evaluation. The interviewer should possess solid knowledge of child sexual development and feel comfortable asking difficult questions of the child and the family. The interviewer should be aware of his or her own biases while interviewing and avoid assuming the abuse is all bad or painful, or that the victim is angry with the perpetrator (Schetky and Green 2014). According to Vizard (2013), an "assessment triangle," including the child's developmental needs, parenting capacity, and family and environmental factors are elements that provide for the framework of assessing the child victim.

ROLE OF THE FORENSIC PRACTITIONER

Forensic psychiatrists are often asked to assess victims and perpetrators of child abuse in legal settings—Dependency Court, Family Court, Criminal Court, and Civil Court. In Dependency Court the question posed to the evaluator might be the fitness of a parent accused of abuse. The evaluator opines about issues regarding visitation, reunification, and risks of further abuse. Additionally, the evaluator might be asked to assess the child victim for recommendations for mental health services and reunification. In Family Court, the child custody evaluator opines about the family dynamics to guide the court about the best interests of the child in various matters such as child abuse claims or domestic violence cases. In Criminal Court the evaluator might be asked to assess the perpetrator regarding potential for rehabilitation, the victim for assessment of abuse, or treatment of the victim or perpetrator. In Civil Court, the forensic evaluator is commonly asked to assess emotional damages due to alleged abuse. These cases are often difficult to assess due to the multifactorial nature of the specific case. The forensic evaluator is often asked to estimate present and future damages related to abuse. Making specific dollar-based predictions is not evidence based and fraught with problems and should be left to the triers of fact—judge and jury. A risk assessment model is best used to indicate future risk factors based on particulars of the case. Bernet and Corwin (2006) proposed using an evidence-based approach as a guide for estimating damages from child sexual abuse cases by asking four questions based on research and integration into the clinical evaluation (see Table 40.6).

Table 40.6 Evidence-based approach for estimating child sexual abuse damages

1. Was the child injured by sexual abuse?
2. Is the child at risk of psychological problems?
3. What treatment is currently recommended?
4. What treatment will be needed in the future?

Forensic practitioners are frequently involved in families where domestic violence is present. Child custody evaluators determine the best interests of the children in the context of exposure to domestic violence by evaluating the children's mental health, safety concerns of children and caregivers, and the dynamics between the domestically violent parent and the victim parent who often share custody. Complex dynamics often present in these high-conflict separations. Assessment of domestic violence in families with children requires a systematic, forensic approach that is evidence based. In family law cases, children are potentially exposed to a domestically violent parent even if they are not the direct victims of abuse. The victim of domestic violence, often one parent, is not always present to protect the children when custody is shared, thereby exposing the children to a potentially violent parent. In some cases, separation of parents is a safety factor and significantly reduces the risk of exposing the children to future violence.

LONG-TERM EFFECTS OF CHILD MALTREATMENT

The consequences of child maltreatment have been shown to affect victims throughout their life span from childhood to adulthood. Child abuse and neglect may affect a person's physical, cognitive, emotional, and behavioral development, thus disrupting the possibility of living a normal life. Goldman (2003) discussed three overlapping areas where the effects of child abuse and neglect lead to problems: health and physical well-being, intellectual and cognitive development, and emotional, psychological, and behavioral consequences.

Not all children are severely affected by abuse. The manifestation of abuse depends on their age and developmental status. McSherry (2011) found both abuse and neglect cause significant academic delays, poor school performance, and a higher incidence of disciplinary actions taken against these children. There are causal relationships between nonsexual child maltreatment and a range of mental disorders, drug use, suicidality, and promiscuity (Norman et al. 2012).

Children and adolescents are at risk of developing depressive disorders, conduct disorders, psychotic symptoms, suicidality, risky sexual behavior, substance abuse, and cigarette smoking (Norman et al. 2012; Arseneault et al. 2014; Kaplan et al. 2014). A history of abuse in childhood increases the likelihood of lifetime psychopathology. This association appears stronger for women than men (Macmillan et al. 2014). In adults abused as children, there is an increased risk of substance abuse, anxiety, depression, suicidality, dissociative disorders, and eating disorders (Herrenkohl et al. 2013; Chu et al. 2014; Johnson et al. 2014; McHolm et al. 2014).

Child sexual abuse is associated with 47% of all childhood-onset psychiatric disorders and with 26%–32% of adult-onset disorders (Wilsnack et al. 1997; Green et al. 2010; Pérez-Fuentes et al. 2013). Being raped, knowing the perpetrator, and a higher frequency of abuse are associated with increased risks of psychiatric disorders (Finkelhor and Browne 1985; Pérez-Fuentes et al. 2013). Abuse involving penetration and abuse by a father or stepfather carries greater risk of long-term harm (Beitchman et al. 1992).

There is no specific pathognomonic or psychopathological syndrome associated with child sexual abuse in adulthood. However, there is a plethora of long-term sequelae including increased probability of being widowed, separated, and divorced (Finkelhor et al. 1990), relationship problems, and psychiatric disorders, especially PTSD and mood disorders.

SUMMARY

Child maltreatment remains a serious and prevalent problem, with millions of children being abused worldwide. A proliferation of research, especially in the area of child witnesses and child sexual abuse, has led to the development of interview protocols and guidelines. Many agencies have devised their own protocols. Further research and revisions of the numerous protocols for interviewing are required to devise a uniform protocol to be used by all agencies. The NICHD protocol is a prime example of international collaboration, and training programs for the protocol are offered in over a dozen languages.

Victims of child sex trafficking and child pornography are difficult to identify due to the clandestine world in which the perpetrators dwell. Identifying the signs indicating these serious crimes is important. Children exposed to domestic violence often do not have visible scars, but their developmental trajectory is derailed. An emphasis on keeping children safe while repairing the damage from domestic violence is needed. Treatment protocols for child maltreatment victims, especially in the mental health arena, require further research.

Continued education of social services and medical personnel is needed to identify, evaluate, and treat victims of child maltreatment. Public awareness campaigns are important to educate the public about parenting and safe child-rearing practices. Many risk factors for child maltreatment are complicated sociological problems such as poverty, lack of education, and unemployment that ultimately perpetuate the cycle of abuse. Prevention rather than reaction is key in reducing the prevalence of child abuse.

Juvenile delinquency

EILEEN P. RYAN

INTRODUCTION

Juvenile delinquency is a significant societal problem. Juveniles accounted for 13% of all violent crime arrests and 22% of all property crime arrests in 2011 (Puzzanchera 2013). The definition of juvenile delinquency varies depending on the local jurisdiction, but the traditional definition of a juvenile delinquent is someone under the age of 18 who is found to have committed a crime (adjudicated) in states in which it is declared by law that the minor's culpability is less than that of an adult, precluding sentencing as an adult.

This chapter will explore the history of juvenile justice in the United States, recent trends in our perceptions and treatment of juvenile offenders, risk factors for delinquency, mental health issues in this population, empirically based effective interventions, and prognosis for youthful offenders.

JUVENILE JUSTICE IN THE UNITED STATES

Juvenile courts deal with minors accused of violating a criminal statute, and the proceedings are civil as opposed to criminal. Therefore, instead of being charged with a crime, youth are accused of committing a delinquent act. The first juvenile court was established in Chicago in 1899, in large part due to the efforts of reformers such as Jane Adams, who also co-founded Hull House, a settlement house offering supportive services to the poor, especially the local immigrant population. Immigrant children living in poverty had higher involvement in criminal activity. Prior to the establishment of the juvenile court, young "hooligans" were subject to the same penalties as adult criminals and housed in adult jails.

In the name of *parens patriae* (*Prince v. Massachusetts* 1944), the state could act as a parent, and juvenile court judges were allowed to intervene in whatever manner was deemed by the court to be in the best interests of the child. The juvenile court offered none of the legal protections (e.g., right to an attorney, right to examine witnesses, etc.) offered to adults because its goal was not criminal, but rehabilitative. Judge Julian Mack, America's first juvenile judge, proposed in a *Harvard Law Review* article (Mack 1909) that the juvenile offender should be treated "as a wise and merciful father handles his own child." In keeping with the rehabilitative nature of the juvenile court, a different descriptive terminology was developed. Juveniles are not arrested; they are "taken into custody." They are not convicted at trials; they are "adjudicated" at hearings. Rather than sentenced, adjudicated delinquents are given "dispositions." Status offenses are those acts that would not be characterized as offenses if the perpetrator were an adult, for example, possession of tobacco products, truancy, and curfew violation.

LANDMARK CASES AND LEGISLATION IN JUVENILE JUSTICE

Unfortunately the promise of rehabilitation gave way to the reality of reform and training schools, many of which were not rehabilitative, and some of which were abusive. These facilities typically emphasized work and minimized the role of education or treatment. In *Kent,* the Supreme Court put an end to the unchecked powers of the juvenile court. Although it has been lamented that the Supreme Court decision in *Kent v. United States* (1966, 541) marked the beginning of the criminalization of the juvenile court (Quinn 2002, 719–730), juvenile courts had become small fiefdoms in which judges had extremely wide latitude.

In 1961 in Washington, DC, Morris Kent was 16 years old and already on probation for a variety of offenses when he was charged with rape and robbery. At that time, the Juvenile Court Act required a "full investigation" prior to waiving a juvenile to the adult system. The juvenile court judge did not rule on Kent's attorney's motion requesting a hearing and stated the court was waiving jurisdiction to adult criminal court after making a full investigation. However, the judge did not describe the nature of the investigation or the grounds for the waiver. Kent was found not guilty by reason of insanity (NGRI) for the rape, but guilty of housebreaking and robbery. He was subsequently sentenced to 30 to 90 years in prison. The Supreme Court ruled

the waiver invalid, asserting that Kent was entitled to "the essentials of due process and fair treatment." In the majority opinion, Justice Abe Fortas observed that juveniles had "the worst of both worlds," getting "neither the protections accorded to adults, nor the solicitous care and regenerative treatment postulated for children."

The Supreme Court decision *In re Gault* (1967) followed closely on the heels of *Kent*. Gerald Gault was a 15-year-old boy in Arizona on probation for a minor property offense when he and his friend were accused by a neighbor of making an obscene phone call. Gault and his parents never saw the report filed by the probation officer, listing the charge as making lewd phone calls. At his hearing the neighbor was not present, no transcript of the hearing was made, and no one was sworn in to testify. For an offense for which as an adult the maximum sentence would have been a $50 fine or 2 months in jail, Gault was remanded to a training school for the remainder of his minority (ostensibly until age 21). The U.S. Supreme Court took the case, and writing for the majority, Justice Fortas noted, "Under our Constitution, the condition of being a boy does not justify a kangaroo court." The Court ruled juveniles have the right to notice of charges, an attorney, a hearing, and the privilege against self-incrimination, and the right to confront their accusers and cross-examine witnesses.

Given that juvenile court is not considered criminal court, prior to 1970 the standard of proof was preponderance of the evidence. The Supreme Court ruled in *In re Winship*, given the significant liberty interest at stake, the standard of proof should be beyond a reasonable doubt (*In re Winship* 1970). *Breed v. Jones* in 1975 established a juvenile's right to be free from double jeopardy (not to be tried in both juvenile and adult court for the same crime). However, in 1971, the Supreme Court refused to grant juveniles the right to a jury trial, noting the juvenile court remains at its core a tool for rehabilitation, and expressing a reluctance to turn it into a younger version of adult criminal court. The same rationale was used again in 1984, when the Supreme Court upheld pretrial preventative detention, indicating juveniles have no constitutional right to bail or to a speedy trial.

The Juvenile Justice and Delinquency Prevention Act passed in 1974 was designed to improve the handling of youth by the juvenile courts (Public Law No. 93-415, 1974) and has four core provisions. The Act: (1) focused on removing juveniles from adult lock-ups; (2) mandated the "sight-and sound" separation of incarcerated youth from adult inmates; (3) directed states to address the issue of disproportionate minority incarceration; and (4) directed de-institutionalization of status offenses. The Act was amended in 2002 and reflected the increased emphasis on "accountability" but was not substantively changed from the 1974 legislation (Juvenile Justice and Delinquency Prevention Act of 2002).

JUVENILE CRIME TRENDS

A sharp increase in juvenile crime in the late 1980s and early 1990s resulted in a shift in public opinion and public policy (Scott and Steinberg 2008, 4–13). State legislatures across the United States began to move away from the traditional emphasis on rehabilitation in the juvenile justice system and toward more harsh and punitive measures. By 2003, 31 states had enacted automatic transfer statutes requiring juvenile offenders with certain charges to be tried as adults (Steiner and Hemmens 2003). Also, the age at which juvenile court jurisdiction ended was lowered in 13 states to age 15 or 16 years (Snyder and Sickmund 2006).

Transfer laws were intended as a deterrent to juvenile crime and to effect a reduction in the rate of recidivism. Research on the specific deterrence effect of transfer laws has consistently indicated higher rates of recidivism for juveniles convicted in criminal courts versus their counterparts adjudicated for similar crimes in the juvenile courts; however, whether they deter potential juvenile offenders is less clear (Redding 2010).

Juvenile crime peaked in the early 1990s and has been falling since. According to national crime statistics reported by the Office of Juvenile Justice and Delinquency Prevention, the number of juvenile arrests for aggravated assault in 2011 was half of what it was in 1994. Between 1994 and 2010, the violent crime arrest rate decreased 55% to its lowest level since 1980 (Puzzanchera 2013). There is no consensus on the reasons for this decline, although a variety of explanations have been offered, including improved policing and youth initiatives, and a decrease in the demand for crack cocaine, which peaked in the 1990s (Sickmund and Puzzanchera 2014).

CAUSES AND RISK FACTORS FOR DELINQUENCY
